Note the following details of the code protection feature on PICmicro® MCUs.

- The PICmicro family meets the specifications contained in the Microchip Data Sheet.
- Microchip believes that its family of PICmicro microcontrollers is one of the most secure products of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the PICmicro microcontroller in a manner outside the operating specifications contained in the data sheet. The person doing so may be engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as "unbreakable".
- Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our product.

If you have any further questions about this matter, please contact the local sales office nearest to you.

INTRODUCTION

This document discusses the technical details of the MPLAB C18 compiler. This document will explain all functionality of the MPLAB C18 compiler. It assumes that the programmer already:

- knows how to write C programs
- knows how to use the MPLAB Integrated Development Environment (IDE) to create and debug projects
- has read and understands the processor data sheet for which code is being written

ABOUT THIS GUIDE

Document Layout

The document layout is as follows:

- **Chapter 1:** Provides an overview of the MPLAB C18 compiler and information on invoking the compiler.
- **Chapter 2:** Discusses how the MPLAB C18 compiler differs from the ANSI standard.
- **Chapter 3:** Discusses how the MPLAB C18 compiler utilizes the resources of the PIC18 PICmicro® microcontrollers.
- **Chapter 4:** Discusses the optimizations that are performed by the MPLAB C18 compiler.
- **Chapter 5:** Provides a sample application and describes the source code with references to the specific topics discussed in the User's Guide.
Conventions Used in this Guide

This User's Guide uses the following documentation conventions:

**RECOMMENDED READING**

**PIC18 Development References**

**MPLAB C18 Getting Started Guide (DS51295)** describes how to install the MPLAB C18 compiler, how to write simple programs and how to use the MPLAB IDE with the compiler.

**MPLAB C18 Compiler Libraries (DS51297)** lists all library functions provided with the MPLAB C18 compiler with detailed descriptions of their use.

**MPLAB IDE User's Guide (DS51025)** describes how to use the MPLAB IDE, including how to create projects and debug projects.

**MPLAB IDE V6.XX Quick Start Guide (DS51281)** describes how to set up the MPLAB IDE software and use it to create projects and program devices.

**MPASM User's Guide with MPLINK and MPLIB (DS33014)** describes how to use the Microchip PICmicro MCU assembler (MPASM), linker (MPLINK) and librarian (MPLIB).

**Technical Library CD-ROM (DS00161)** contains comprehensive application notes, data sheets and technical briefs for all Microchip products.

To obtain any of the above listed documents, contact the nearest Microchip Sales and Service location (see back page) or visit the Microchip web site (www.microchip.com) to retrieve these documents in Adobe Acrobat (.pdf) format.
C References

This standard specifies the form and establishes the interpretation of programs expressed in the programming language C. Its purpose is to promote portability, reliability, maintainability and efficient execution of C language programs on a variety of computing systems.

Focuses on Microchip Technology’s PIC18FXXX family and writing enhanced application code.

Covers the C programming language in great detail. This book is an authoritative reference manual that provides a complete description of the C language, the run-time libraries and a style of C programming that emphasizes correctness, portability and maintainability.

Presents a concise exposition of C as defined by the ANSI standard. This book is an excellent reference for C programmers.

Another excellent reference for learning ANSI C, used in colleges and universities.

Although this book focuses on Motorola microcontrollers, the basic principles of programming with C for microcontrollers is useful.
NOTES:
1.1 OVERVIEW

The MPLAB C18 compiler is a free-standing, optimizing ANSI C compiler for the PIC18 PICmicro microcontrollers (MCU). The compiler deviates from the ANSI standard X3.159-1989 only where the standard conflicts with efficient PICmicro MCU support. The compiler is a 32-bit Windows® console application and is fully compatible with Microchip's MPLAB IDE, allowing source-level debugging with the MPLAB ICE in-circuit emulator, the MPLAB ICD 2 in-circuit debugger or the MPLAB SIM simulator. The MPLAB C18 compiler has the following features:

- ANSI '89 compatibility
- Integration with the MPLAB IDE for easy-to-use project management and source-level debugging
- Generation of relocatable object modules for enhanced code reuse
- Compatibility with object modules generated by the MPASM assembler, allowing complete freedom in mixing assembly and C programming in a single project
- Transparent read/write access to external memory
- Strong support for inline assembly when total control is absolutely necessary
- Efficient code generator engine with multi-level optimization
- Extensive library support, including PWM, SPI, I2C, UART, USART, string manipulation and math libraries
- Full user-level control over data and code memory allocation

1.2 INVOKING THE COMPILER

The *MPLAB C18 Getting Started Guide* (DS51295) describes how to use the compiler with the MPLAB IDE. The compiler can also be invoked from the command line. The command-line usage is:

```
mcc18 [options] file [options]
```

A single source file and any number of command-line options can be specified. The `--help` command-line option lists all command-line options accepted by the compiler. The `-verbose` command-line option causes the compiler to show a banner containing the version number and the total number of errors, warnings and messages upon completion.
1.2.1 Creating Output Files

By default, the compiler will generate an output object file named file.o, where file is the name of the source file specified on the command line minus the extension. The output object file name can be overridden with the -fo command-line option. For example:

```
mcc18 -fo bar.o foo.c
```

If the source file contains errors, then the compiler generates an error file named file.err, where file is the name of the source file specified on the command line minus the extension. The error file name can be overridden using the -fe command-line option. For example:

```
mcc18 -fe bar.err foo.c
```

1.2.2 Displaying Diagnostics

Diagnostics can be controlled using the -w and -nw command-line options. The -w command-line option sets the level of warning diagnostics (1, 2 or 3). Table 1-1 shows the level of warning diagnostics and the type of diagnostics that are shown. The -nw command-line option suppresses specific messages (Appendix D or the --help-message-list command-line option lists all messages generated by the compiler). Help on all messages can be seen using the --help-message-all command-line option. For help on a specific diagnostic, the --help-message command-line option can be used. For example:

```
mcc18 --help-message=2068
```

displays the following results:

2068: obsolete use of implicit 'int' detected.

The ANSI standard allows a variable to be declared without a base type being specified, e.g., "extern x;", in which case a base type of 'int' is implied. This usage is deprecated by the standard as obsolete, and therefore a diagnostic is issued to that effect.

<table>
<thead>
<tr>

</thead>
<tbody>
<tr>
<td>1</td>
<td>Errors (fatal and non-fatal)</td>
</tr>
<tr>
<td>2</td>
<td>Level 1 plus warnings</td>
</tr>
<tr>
<td>3</td>
<td>Level 2 plus messages</td>
</tr>
</tbody>
</table>
1.2.3 Defining Macros

The `-D` command-line option allows a macro to be defined. The `-D` command-line option can be specified in one of two ways: `-D name` or `-D name=value`. `-D name` defines the macro `name` with 1 as its definition. `-D name=value` defines the macro `name` with value as its definition. For example:

```
mcc18 -DMODE
```

defines the macro `MODE` to have a value of 1, whereas:

```
mcc18 -DMODE=2
```

defines the macro `MODE` to have a value of 2.

An instance of utilizing the `-D` command-line option is in conditional compilation of code. For example:

```
#if MODE == 1
    x = 5;
#elif MODE == 2
    x = 6;
#else
    x = 7;
#endif
```

1.2.4 Selecting the Processor

By default, MPLAB C18 compiles an application for a generic PIC18 PICmicro microcontroller. The object file can be limited to a specific processor with the `-p` `processor` command-line option, where `processor` specifies the particular processor to utilize. For example, to limit an object file for use with only the PIC18F452, the command-line option `-p18f452` should be used. The command-line option `-p18cxx` explicitly specifies that the source is being compiled for a generic PIC18 PICmicro microcontroller.

**Note:** Other command-line options are discussed throughout the User’s Guide, and a summary of all the command-line options can be found in Appendix C.
Chapter 2. Language Specifics

2.1 DATA TYPES AND LIMITS

2.1.1 Integer Types

The MPLAB C18 compiler supports the standard ANSI-defined integer types. The ranges of the standard integer types are documented in Table 2-1. In addition, MPLAB C18 supports a 24-bit integer type `short long int` (or `long short int`), in both a signed and unsigned variety. The ranges of this type are also documented in Table 2-1.

TABLE 2-1: INTEGER DATA TYPE SIZES AND LIMITS

<table>
<thead>
<tr>
<th>Type</th>
<th>Size</th>
<th>Minimum</th>
<th>Maximum</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>char</code></td>
<td>8 bits</td>
<td>-128</td>
<td>127</td>
</tr>
<tr>
<td><code>signed char</code></td>
<td>8 bits</td>
<td>-128</td>
<td>127</td>
</tr>
<tr>
<td><code>unsigned char</code></td>
<td>8 bits</td>
<td>0</td>
<td>255</td>
</tr>
<tr>
<td><code>int</code></td>
<td>16 bits</td>
<td>-32768</td>
<td>32767</td>
</tr>
<tr>
<td><code>unsigned int</code></td>
<td>16 bits</td>
<td>0</td>
<td>65535</td>
</tr>
<tr>
<td><code>short</code></td>
<td>16 bits</td>
<td>-32768</td>
<td>32767</td>
</tr>
<tr>
<td><code>unsigned short</code></td>
<td>16 bits</td>
<td>0</td>
<td>65535</td>
</tr>
<tr>
<td><code>short long</code></td>
<td>24 bits</td>
<td>-8,388,608</td>
<td>8,388,607</td>
</tr>
<tr>
<td><code>unsigned short long</code></td>
<td>24 bits</td>
<td>0</td>
<td>16,777,215</td>
</tr>
<tr>
<td><code>long</code></td>
<td>32 bits</td>
<td>-2,147,483,648</td>
<td>2,147,483,647</td>
</tr>
<tr>
<td><code>unsigned long</code></td>
<td>32 bits</td>
<td>0</td>
<td>4,294,967,295</td>
</tr>
</tbody>
</table>

Note 1: A plain `char` is signed by default.

2: A plain `char` may be unsigned by default via the `-k` command-line option.

2.1.2 Floating-Point Types

32-bit floating-point types are native to MPLAB C18 using either the `double` or `float` data types. The ranges of the floating-point type are documented in Table 2-2.

TABLE 2-2: FLOATING-POINT DATA TYPE SIZES AND LIMITS

<table>
<thead>
<tr>
<th>Type</th>
<th>Size</th>
<th>Minimum Exponent</th>
<th>Maximum Exponent</th>
<th>Minimum Normalized</th>
<th>Maximum Normalized</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>float</code></td>
<td>32 bits</td>
<td>-126</td>
<td>128</td>
<td>(2^{-126} = 1.17549435e - 38) (2^{128} \times (2^{-2^{-15}}) \approx 6.80564693e^{38})</td>
<td></td>
</tr>
<tr>
<td><code>double</code></td>
<td>32 bits</td>
<td>-126</td>
<td>128</td>
<td>(2^{-126} = 1.17549435e - 38) (2^{128} \times (2^{-2^{-15}}) \approx 6.80564693e^{38})</td>
<td></td>
</tr>
</tbody>
</table>
The MPLAB C18 format for floating-point numbers is a modified form of the IEEE 754 format. The difference between the MPLAB C18 format and the IEEE 754 format consists of a rotation of the top nine bits of the representation. A left rotate will convert from the IEEE 754 format to the MPLAB C18 format. A right rotate will convert from the MPLAB C18 format to the IEEE 754 format. Table 2-3 compares the two formats.

**TABLE 2-3: MPLAB C18 FLOATING-POINT VS. IEEE 754 FORMAT**

<table>
<thead>
<tr>
<th></th>
<th>Standard</th>
<th>Exponent Byte</th>
<th>Byte 0</th>
<th>Byte 1</th>
<th>Byte 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE 754</td>
<td>s e_0 e_1 e_2 e_3 e_4 e_5 e_6</td>
<td>e_7 dddd dddd</td>
<td>dddd dddd</td>
<td>dddd dddd</td>
<td></td>
</tr>
<tr>
<td>MPLAB C18</td>
<td>e_0 e_1 e_2 e_3 e_4 e_5 e_6 e_7</td>
<td>sddd dddd</td>
<td>dddd dddd</td>
<td>dddd dddd</td>
<td></td>
</tr>
</tbody>
</table>

**Legend:**
- s = sign bit
- d = mantissa
- e = exponent

### 2.2 DATA TYPE STORAGE - ENDIANNESS

Endianness refers to the ordering of bytes in a multi-byte value. MPLAB C18 stores data in little-endian format. Bytes at lower addresses have lower significance (the value is stored “little-end-first”). For example:

```c
#pragma idata test=0x0200
long l=0xAABBCCDD;
```

results in a memory layout as follows:

<table>
<thead>
<tr>
<th>Address</th>
<th>0x0200</th>
<th>0x0201</th>
<th>0x0202</th>
<th>0x0203</th>
</tr>
</thead>
<tbody>
<tr>
<td>Content</td>
<td>0xDD</td>
<td>0xCC</td>
<td>0xBB</td>
<td>0xAA</td>
</tr>
</tbody>
</table>
2.3 STORAGE CLASSES

MPLAB C18 supports the ANSI standard storage classes (auto, extern, register, static and typedef).

2.3.1 Overlay

The MPLAB C18 compiler introduces a storage class of overlay. The overlay storage class may be applied to local variables (but not formal parameters, function definitions or global variables). The overlay storage class will allocate the associated symbols into a function-specific, static overlay section. Such a variable will be allocated statically, but initialized upon each function entry. For example, in:

```c
void f (void)
{
    overlay int x = 5;
    x++; 
}
```

`x` will be initialized to 5 upon each function entry, although its storage will be statically allocated. If no initializer is present, then its value upon function entry is undefined.

The MPLINK linker will attempt to overlay local storage specified as overlay from functions that are guaranteed not to be active simultaneously. For example, in:

```c
int f (void)
{
    overlay int x = 1;
    return x;
}

int g (void)
{
    overlay int y = 2;
    return y;
}
```

if `f` and `g` will never be active at the same time, `x` and `y` become candidates for sharing the same memory location. However, in:

```c
int f (void)
{
    overlay int x = 1;
    return x;
}

int g (void)
{
    overlay int y = 2;
    y = f ( );
    return y;
}
```

since `f` and `g` may be simultaneously active, `x` and `y` will not be overlaid. The advantage of using overlay locals is that they are statically allocated, which means that, in general, fewer instructions are required to access them (resulting in a smaller program memory image). At the same time, the total data memory allocation required for these variables may be less than what would be required had they been declared as static due to the fact that some of the variables may be overlaid.
If the MPLINK linker detects a recursive function that contains a local variable of storage class `overlay`, it emits an error and aborts. If the MPLINK linker detects a call through a function pointer in any module and a local variable of storage class `overlay` in any (and not necessarily the same) module, it emits an error and aborts.

The default storage class for local variables is `auto`. This can be overridden explicitly with the `static` or `overlay` keywords or implicitly with either the `-scs (static local variables)` or `-sco (overlay local variables)` command-line option. For completeness, MPLAB C18 also supports the `-sca` command-line option. This option allows the storage class for local variables to be explicitly specified as `auto`.

### 2.3.2 `static` Function Arguments

Function parameters can have storage class `auto` or `static`. An `auto` parameter is placed on the software stack, enabling reentrancy. A `static` parameter is allocated globally, enabling direct access for generally smaller code.

The default storage class for function parameters is `auto`. This can be overridden explicitly with the `static` keyword or implicitly with the `-scs` command-line option. The `-sco` command-line option will also implicitly override function parameters' storage class with `static`.

### 2.4 STORAGE QUALIFIERS

In addition to the ANSI standard storage qualifiers (`const`, `volatile`), the MPLAB C18 compiler introduces storage qualifiers of `far`, `near`, `rom` and `ram`. Syntactically, these new qualifiers bind to identifiers just as the `const` and `volatile` qualifiers do in ANSI C. Table 2-4 shows the location of an object based on the storage qualifiers specified when it was defined. The default storage qualifiers for an object defined without explicit storage qualifiers are `far` and `ram`.

**TABLE 2-4: LOCATION OF OBJECT BASED ON STORAGE QUALIFIERS**

<table>
<thead>
<tr>
<th></th>
<th>rom</th>
<th>ram</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>far</code></td>
<td>Anywhere in program memory</td>
<td>Anywhere in data memory (default)</td>
</tr>
<tr>
<td><code>near</code></td>
<td>In program memory with address less than 64K</td>
<td>In access memory</td>
</tr>
</tbody>
</table>

#### 2.4.1 `near`/`far` Data Memory Objects

The `far` qualifier is used to denote that a variable that is located in data memory lives in a memory bank and that a bank switching instruction is required prior to accessing this variable. The `near` qualifier is used to denote that a variable located in data memory lives in access RAM.

#### 2.4.2 `near`/`far` Program Memory Objects

The `far` qualifier is used to denote that a variable that is located in program memory can be found anywhere in program memory, or, if a pointer, that it can access up to and beyond 64K of program memory space. The `near` qualifier is used to denote that a variable located in program memory is found at an address less than 64K, or, if a pointer, that it can access only up to 64K of program memory space.
2.4.3 **ram/rom Qualifiers**

Because the PICmicro microcontrollers use separate program memory and data memory address busses in their design, MPLAB C18 requires extensions to distinguish between data located in program memory and data located in data memory. The ANSI/ISO C standard allows for code and data to be in separate address spaces, but this is not sufficient to locate data in the code space as well. To this purpose, MPLAB C18 introduces the `rom` and `ram` qualifiers. The `rom` qualifier denotes that the object is located in program memory, whereas the `ram` qualifier denotes that the object is located in data memory.

Pointers can point to either data memory (`ram` pointers) or program memory (`rom` pointers). Pointers are assumed to be `ram` pointers unless declared as `rom`. The size of a pointer is dependent on the type of the pointer and is documented in Table 2-5.

<table>
<thead>
<tr>
<th>Pointer Type</th>
<th>Example</th>
<th>Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data memory pointer</td>
<td>char * dmp;</td>
<td>16 bits</td>
</tr>
<tr>
<td>Near program memory pointer</td>
<td>rom near * npmp;</td>
<td>16 bits</td>
</tr>
<tr>
<td>Far program memory pointer</td>
<td>rom far * fpmp;</td>
<td>24 bits</td>
</tr>
</tbody>
</table>

**Note:** When writing to a `rom` variable, the compiler uses a `TBLWT` instruction; however, there may be additional application code that needs to be written based on the type of memory being utilized. See the data sheet for more information.

2.5 **INCLUDE FILE SEARCH PATHS**

2.5.1 **System Header Files**

Source files included with `#include <filename>` are searched for in the path specified in the `MCC_INCLUDE` environment variable and the directories specified via the `-I` command-line option. Both the `MCC.Include` environment variable and the `-I` values are a semi-colon delimited list of directories to search. If the included file exists in both a directory listed in the `MCC_INCLUDE` environmental variable and a directory listed in a `-I` command-line option, the file will be included from the directory listed in the `-I` command-line option. This allows the `MCC_INCLUDE` environmental variable to be overridden with a `-I` command-line option.

2.5.2 **User Header Files**

Source files included with `#include "filename"` are searched for in the directory containing the including file. If not found, the file is searched for as a system header file (see 2.5.1 “System Header Files”).
2.6 PREDEFINED MACRO NAMES

In addition to the standard predefined macro names, MPLAB C18 provides the following predefined macros:

- __18CXX__ The constant 1, intended to indicate the MPLAB C18 compiler.
- __PROCESSOR__ The constant 1 if compiled for the particular processor. For example, __18C452__ would be defined as the constant 1 if compiled with the -p18c452 command-line option and __18F258__ would be defined as the constant 1 if compiled with the -p18f258 command-line option.
- __SMALL__ The constant 1 if compiled with the -ms command-line option.
- __LARGE__ The constant 1 if compiled with the -ml command-line option.

2.7 ISO DIVERGENCES

2.7.1 Integer Promotions

ISO mandates that all arithmetic be performed at int precision or greater. By default, MPLAB C18 will perform arithmetic at the size of the largest operand, even if both operands are smaller than an int. The ISO mandated behavior can be instated via the -Oi command-line option.

For example:

```c
unsigned char a, b;
unsigned i;

a = b = 0x80;
i = a + b; /* ISO requires that i == 0x100, but in C18 i == 0 */
```

Note that this divergence also applies to constant literals. The chosen type for constant literals is the first one from the appropriate group that can represent the value of the constant without overflow.

For example:

```c
#define A 0x10 /* A will be considered a char unless -Oi specified */
#define B 0x10 /* B will be considered a char unless -Oi specified */
#define C (A) * (B)

unsigned i;
i = C; /* ISO requires that i == 0x100, but in C18 i == 0 */
```

2.7.2 Numeric Constants

MPLAB C18 supports the standard prefixes for specifying hexadecimal (0x) and octal (0) values and adds support for specifying binary values using the 0b prefix. For example, the value two hundred thirty seven may be denoted as the binary constant 0b11101101.
2.7.3 String Constants

The primary use of data located in program memory is for static strings. In keeping with this, MPLAB C18 automatically places all string constants in program memory. This type of a string constant is “array of char located in program memory”, (const rom char []). The .stringtable section is a romdata (see 2.9.1 “pragma sectiontype”) section that contains all constant strings. For example the string “hello” in the following would be located in the .stringtable section:

```c
strcppgm2ram (Foo, “hello”);
```

Due to the fact that constant strings are kept in program memory, there are multiple versions of the standard functions that deal with strings. For example, the strcpy function has four variants, allowing the copying of a string to and from data and program memory:

```c
/*
 * Copy string s2 in data memory to string s1 in data memory
 */
char *strcpy (auto char *s1, auto const char *s2);

/*
 * Copy string s2 in program memory to string s1 in data
 * memory
 */
char *strcppgm2ram (auto char *s1, auto const rom char *s2);

/*
 * Copy string s2 in data memory to string s1 in program
 * memory
 */
rom char *strcpyram2pgm (auto rom char *s1, auto const char *s2);

/*
 * Copy string s2 in program memory to string s1 in program
 * memory
 */
rom char *strcppgm2pgm (auto rom char *s1,
                        auto const rom char *s2);
```

When using MPLAB C18, a string table in program memory can be declared as:

```c
rom const char table[][20] = { “string 1”, “string 2”,
                              “string 3”, “string 4”
                           };
rom const char *rom table2[] = { “string 1”, “string 2”,
                                “string 3”, “string 4”
                             };
```

The declaration of table declares an array of four strings that are each 20 characters long, and so takes 80 bytes of program memory. table2 is declared as an array of pointers to program memory. The rom qualifier after the * places the array of pointers in program memory as well. All of the strings in table2 are 9 bytes long, and the array is four elements long, so table2 takes (9*4+4*2) = 44 bytes of program memory. Accesses to table2 may be less efficient than accesses to table, however, because of the additional level of indirection required by the pointer.
An important consequence of the separate address spaces for MPLAB C18 is that pointers to data in program memory and pointers to data in data memory are not compatible. Two pointer types are not compatible unless they point to objects of compatible types and the objects they point to are located in the same address space. For example, a pointer to a string in program memory and a pointer to a string in data memory are not compatible because they refer to different address spaces.

A function to copy a string from program to data memory could be written as follows:

```c
void str2ram(void *dest, void *src)
{
    while (((*dest++) = (*src++)) != '\0')
        ;
}
```

The following code will send a string located in program memory to the USART on a PIC18C452 using the PICmicro MCU C libraries. The library function to send a string to the USART, `putsUSART(const char *str)`, takes a pointer to a string as its argument, but that string must be in data memory.

```c
rom char mystring[] = "Send me to the USART";

void foo(void)
{
    char strbuffer[21];
    str2ram(strbuffer, mystring);
    putsUSART(strbuffer);
}
```

Alternatively, the library routine can be modified to read from a string located in program memory.

```c
/*
 * The only changes required to the library routine are to
 * change the name so the new routine does not conflict with
 * the original routine and to add the rom qualifier to the
 * parameter.
 */
void putsUSART_rom(void *data)
{
    /* Send characters up to the null */
    do
    {
        while (BusyUSART())
            ;

        /* Write a byte to the USART */
        putcUSART(*data);
    } while (*data++);
}
```
2.8 LANGUAGE EXTENSIONS

2.8.1 Anonymous Structures

MPLAB C18 supports anonymous structures inside of unions. An anonymous structure has the form:

```c
struct { member-list };
```

An anonymous structure defines an unnamed object. The names of the members of an anonymous structure must be distinct from other names in the scope in which the structure is declared. The members are used directly in that scope without the usual member access syntax.

For example:

```c
union foo
{
    struct
    {
        int a;
        int b;
    };
    char c;
} bar;
```

```c
... bar.a = bar.c; /* 'a' is a member of the anonymous structure located inside 'bar' */
```

A structure for which objects or pointers are declared is not an anonymous structure. For example:

```c
union foo
{
    struct
    {
        int a;
        int b;
    } f, *ptr;
    char c;
} bar;
```

```c
... bar.a = bar.c;      /* error */
bar.ptr->a = bar.c; /* ok */
```

The assignment to `bar.a` is illegal since the member name is not associated with any particular object.
2.8.2 Inline Assembly

MPLAB C18 provides an internal assembler using a syntax similar to the MPASM assembler. The block of assembly code must begin with _asm and end with _endasm. The syntax within the block is:

[label:] [<instruction> [arg1[, arg2[, arg3]]]]

The internal assembler differs from the MPASM assembler as follows:

- No directive support
- Comments must be C or C++ notation
- Full text mnemonics must be used for table reads/writes. i.e.,
  - TBLRD
  - TBLRDPOSTDEC
  - TBLRDPOSTINC
  - TBLRDPREINC
  - TBLWT
  - TBLWTPOSTDEC
  - TBLWTPOSTINC
  - TBLWTPREINC
- No defaults for instruction operands – all operands must be fully specified
- Default radix is decimal.
- Literals are specified using C radix notation, not MPASM assembler notation. For example, a hex number should be specified as 0x1234, not H‘1234.’
- Label must include colon

For example:

```asm
/* User assembly code */
MOV LW 10       // Move decimal 10 to count
MOVWF count, 0

/* Loop until count is 0 */
start:
    DECFSZ count, 1, 0
    GOTO done
    BRA start
done:
``` _endasm

It is generally recommended to limit the use of inline assembly to a minimum. Any functions containing inline assembly will not be optimized by the compiler. To write large fragments of assembly code, use the MPASM assembler and link the modules to the C modules using the MPLINK linker.
Language Specifics

2.9 PRAGMAS

2.9.1 #pragma sectiontype

The section declaration pragmas change the current section into which MPLAB C18 will allocate information of the associated type.

A section is a portion of an application located at a specific address of memory. Sections can contain code or data. A section can be located in either program or data memory. There are two types of sections for each type of memory.

- program memory
  - code – contains executable instructions.
  - romdata – contains variables and constants.

- data memory
  - udata – contains statically allocated uninitialized user variables.
  - idata – contains statically allocated initialized user variables.

Sections are absolute, assigned or unassigned. An absolute section is one that is given an explicit address via the =address of the section declaration pragma. An assigned section is one that is ascribed to a specific section via the SECTION directive of the linker script. An unassigned section is one that is neither absolute nor assigned.

2.9.1.1 SYNTAX

section-directive:

  # pragma udata [attribute-list] [section-name [=address]]
  | # pragma idata [attribute-list] [section-name [=address]]
  | # pragma romdata [overlay] [section-name [=address]]
  | # pragma code [overlay] [section-name [=address]]

attribute-list:

  attribute
  | attribute-list attribute

attribute:

  access
  | overlay

section-name: C identifier

address: integer constant
2.9.1.2 SECTION CONTENTS

A code section contains executable content, located in program memory. A romdata section contains data allocated into program memory (normally variables declared with the rom qualifier). For additional information on romdata usage (e.g., for memory-mapped peripherals) see the MPLINK portion of the MPASM User's Guide with MPLINK and MPLIB (DS33014). A udata section contains uninitialized global data statically allocated into data memory. Anidata section contains initialized global data statically allocated into data memory.

Table 2-6 shows which section each of the objects in the following example will be located in:

```c
rom int ri;
rom char rc = 'A';

int ui;
char uc;

int ii = 0;
char ic = 'A';

void foobar (void)
{
    static rom int foobar_ri;
    static rom char foobar_rc = 'Z';
    ...
}

void foo (void)
{
    static int foo_ui;
    static char foo_uc;
    ...
}

void bar (void)
{
    static int bar_ii = 5;
    static char bar_ic = 'Z';
    ...
}
```
TABLE 2-6:  OBJECTS’ SECTION LOCATION

<table>
<thead>
<tr>
<th>Object</th>
<th>Section Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>ri</td>
<td>romdata</td>
</tr>
<tr>
<td>rc</td>
<td>romdata</td>
</tr>
<tr>
<td>foobar_ri</td>
<td>romdata</td>
</tr>
<tr>
<td>foobar_rc</td>
<td>romdata</td>
</tr>
<tr>
<td>ui</td>
<td>udata</td>
</tr>
<tr>
<td>uc</td>
<td>udata</td>
</tr>
<tr>
<td>foo_ui</td>
<td>udata</td>
</tr>
<tr>
<td>foo_uc</td>
<td>udata</td>
</tr>
<tr>

<td>code</td>
</tr>
<tr>
<td>bar</td>
<td>code</td>
</tr>
<tr>
<td>foobar</td>
<td>code</td>
</tr>
</tbody>
</table>

2.9.1.3  DEFAULT SECTIONS

A default section exists for each section type in MPLAB C18 (see Table 2-7).

TABLE 2-7:  DEFAULT SECTION NAMES

<table>
<thead>
<tr>
<th>Section Type</th>
<th>Default Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>code</td>
<td>.code_filename</td>
</tr>
<tr>
<td>romdata</td>
<td>.romdata_filename</td>
</tr>
<tr>
<td>udata</td>
<td>.udata_filename</td>
</tr>
<tr>
<td>idata</td>
<td>.idata_filename</td>
</tr>
</tbody>
</table>

NOTE: filename is the name of the object file being generated. For example, "mcc18 foo.c -fo=foo.o" will produce an object file with a default code section named ".code_foo.o".

Specifying a section name that has been previously declared causes MPLAB C18 to resume allocating data of the associated type into the specified section. The section attributes must match the previous declaration, otherwise an error will occur (see Appendix D.1 “Errors”).
A section pragma directive with no name resets the allocation of data of the associated type to the default section for the current module. For example:

```c
/*
 * The following statement changes the current code
 * section to the absolute section high_vector
 */
#pragma code high_vector=0x08
...

/*
 * The following statement returns to the default code
 * section
 */
#pragma code
...
```

When the MPLAB C18 compiler begins compiling a source file, it has default data sections for both initialized and uninitialized data. These default sections are located in either access or non-access RAM depending on whether the compiler was invoked with a -Oa+ option or not, respectively. When a #pragma udata [access] name directive is encountered in the source code, the current uninitialized data section becomes name, which is located in access or non-access RAM depending on whether the optional access attribute was specified. The same is true for the current initialized data section when a #pragma idata [access] name directive is encountered.

Objects are placed in the current initialized data section when an object definition with an explicit initializer is encountered. Objects without an explicit initializer in their definition are placed in the current uninitialized data section. For example, in the following code snippet, i would be located in the current initialized data section and u would be placed in the current uninitialized data section.

```c
int i = 5;
int u;

void main(void)
{
    ...  
}
```

If an object's definition has an explicit far qualifier (see 2.4 “Storage Qualifiers”), the object is located in non-access memory. Similarly, an explicit near qualifier (see 2.4 “Storage Qualifiers”) tells the compiler that the object is located in access memory. If an object's definition has neither the near or far qualifier, the compiler looks at whether the -Oa+ option was specified on the command line.
2.9.1.4 SECTION ATTRIBUTES

The #pragma sectiontype directive may optionally include two section attributes – access or overlay.

2.9.1.4.1 access

The access attribute tells the compiler to locate the specified section in an access region of data memory (see the device data sheets or the PICmicro 18C MCU Family Reference Manual (DS39500) for more on access data memory).

Data sections with the access attribute will be placed into memory regions that are defined as ACCESSBANK in the linker script file. These regions are those accessed via the access bit of an instruction, i.e., no banking is required (see the device data sheet). Variables located in an access section must be declared with the near keyword. For example:

```c
#pragma udata access my_access
/* all accesses to these will be unbanked */
near unsigned char av1, av2;
```

2.9.1.4.2 overlay

The overlay attribute permits other sections to be located at the same physical address. This can conserve memory by locating variables to the same location (as long as both are not active at the same time.) The overlay attribute can be used in conjunction with the access attribute.

Code sections that have the overlay attribute can be located at an address that overlaps other overlay code sections. For example:

```c
#pragma code overlay my_overlay_scn_1=0x1000
...
#pragma code overlay my_overlay_scn_2=0x1000
...
```

Data sections that have the overlay attribute can be located at an address that overlaps other overlay data sections. This feature can be useful for allowing a single data range to be used for multiple variables that are never active simultaneously. For example:

```c
#pragma udata overlay my_overlay_data1=0x1fc
/* 4 bytes will be located at 0x1fc and 0x1fe */
int int_var1, int_var2;

#pragma udata overlay my_overlay_data2=0x1fc
/* 4 bytes will be located at 0x1fc */
long long_var;
```

For more information on the handling of overlay sections see MPASM User's Guide with MPLINK and MPLIB (DS33014).
2.9.1.5 LOCATING CODE

Following a #pragma code directive, all generated code will be assigned to the specified code section until another #pragma code directive is encountered. An absolute code section allows the location of code to a specific address. For example:

```
#pragma code my_code=0x2000
```

will locate the code section `my_code` at program memory address 0x2000.

The linker will enforce that code sections be placed in program memory regions; however, a code section can be located in a specified memory region. The `SECTION` directive of the linker script is used to assign a section to a specific memory region. The following linker script directive assigns code section `my_code1` to memory region `page1`:

```
SECTION NAME=my_code1 ROM=page1
```

2.9.1.6 LOCATING DATA

Data can be placed in either data or program memory with the MPLAB C18 compiler. Data that is placed in on-chip program memory can be read but not written without additional user-supplied code. Data placed in external program memory can generally be either read or written without additional user-supplied code.

For example, the following declares a section for statically allocated uninitialized data (udata) at absolute address 0x120:

```
#pragma udata my_new_data_section=0x120
```

The `rom` keyword tells the compiler that a variable should be placed in program memory. The compiler will allocate this variable into the current `romdata` type section. For example:

```
#pragma romdata const_table
const rom char my_const_array[10] = {0, 1, 2, 3, 4, 5, 6, 7, 8, 9};
```

```
/* Resume allocation of romdata into the default section */
#pragma romdata
```

The linker will enforce that `romdata` sections be placed in program memory regions and that `udata` and `idata` sections be placed in data memory regions; however, a data section can also be located in a specified memory region. The `SECTION` directive of the linker script is used to assign a section to a specific memory region. The following assigns `udata` section `my_data` to memory region `gpr1`:

```
SECTION NAME=my_data RAM=gpr1
```
2.9.2 #pragma interruptlow fname  
#pragma interrupt fname

The interrupt pragma declares a function to be a high-priority interrupt service routine (ISR); the interruptlow pragma declares a function to be a low-priority interrupt service routine.

An interrupt suspends the execution of a running application, saves the current context information and transfers control to an ISR so that the event may be processed. Upon completion of the ISR, previous context information is restored and normal execution of the application resumes. The minimal context saved and restored for an interrupt is WREG, BSR and STATUS. A high-priority interrupt uses the shadow registers to save and restore the minimal context, while a low-priority interrupt uses the software stack to save and restore the minimal context. As a consequence, a high-priority interrupt terminates with a fast “return from interrupt”, while a low-priority interrupt terminates with a normal “return from interrupt”. Two MOVFF instructions are required for each byte of context preserved via the software stack except for WREG, which requires a MOVWF instruction and a MOVF instruction; therefore, in order to preserve the minimal context, a low-priority interrupt has an additional 10-word overhead beyond the requirements of a high-priority interrupt.

Interrupt service routines use a temporary data section that is distinct from that used by normal C functions. Any temporary data required during the evaluation of expressions in the interrupt service routine is allocated in this section and is not overlaid with the temporary locations of other functions, including other interrupt functions. The interrupt pragmas allow the interrupt temporary data section to be named. If this section is not named, the compiler temporary variables are created in an access qualified udata section named fname_tmp. For example:

```c
void foo(void);
...
#pragma interrupt foo
void foo(void)
{
    /* perform interrupt function here */
}
```

The compiler temporary variables for interrupt service routine foo will be placed in the access qualified udata section foo_tmp.
2.9.2.1 SYNTAX

interrupt-directive:

    # pragma interrupt function-name [tmp-section-name] [save=save-list]
    | # pragma interruptlow function-name [tmp-section-name] [save=save-list]

save-list:

    save-specifier
    | save-list, save-specifier

save-specifier:

    symbol-name
    | section(“section-name”)

function-name: C identifier -- names the C function serving as an ISR.

tmp-section-name: C identifier -- names section in which to allocate the ISR’s
temporary data

symbol-name: C identifier -- name variable that will be restored following interrupt
processing

section-name: C identifier with the exception that the first character can be a dot (.) --
names the section that will be restored following interrupt processing

2.9.2.2 INTERRUPT SERVICE ROUTINES

An MPLAB C18 ISR is like any other C function in that it can have local variables
and access global variables; however, an ISR must be declared with no parameters
and no return value since the ISR, in response to a hardware interrupt, is invoked
asynchronously. Global variables that are accessed by both an ISR and mainline
functions should be declared volatile.

ISR's should only be invoked through a hardware interrupt and not from other C
functions. An ISR uses the return from interrupt (RETFIE) instruction to exit from the
function rather than the normal RETURN instruction. Using a fast RETFIE instruction out
of context can corrupt WREG, BSR and STATUS.
2.9.2.3 INTERRUPT VECTORS

MPLAB C18 does not automatically place an ISR at the interrupt vector. Commonly, a GOTO instruction is placed at the interrupt vector for transferring control to the ISR proper. For example:

```c
#include <p18cxxx.h>

void low_isr(void);
void high_isr(void);

/*
 * For PIC18cxxx devices the low interrupt vector is found at
 * 00000018h. The following code will branch to the
 * low_interrupt_service_routine function to handle
 * interrupts that occur at the low vector.
 */
#pragma code low_vector=0x18
void interrupt_at_low_vector(void)
{
   _asm GOTO low_isr _endasm
}
#pragma code /* return to the default code section */

#pragma interruptlow low_isr
void low_isr (void)
{
   /* ... */
}

/*
 * For PIC18cxxx devices the high interrupt vector is found at
 * 00000008h. The following code will branch to the
 * high_interrupt_service_routine function to handle
 * interrupts that occur at the high vector.
 */
#pragma code high_vector=0x08
void interrupt_at_high_vector(void)
{
   _asm GOTO high_isr _endasm
}
#pragma code /* return to the default code section */

#pragma interrupt high_isr
void high_isr (void)
{
   /* ... */
}
```

For a complete example, see Chapter 5.
2.9.2.4 ISR CONTEXT SAVING

MPLAB C18 will preserve a basic context by default (see 3.4 “Compiler-Managed Resources”), and the `save=` clause allows additional arbitrary symbols to be saved and restored by the function. If the ISR changes any file registers other than the basic context, then they should be named in the `save=` clause. The generated code should be examined to determine which file registers are used and need to be saved.

```
#pragma interrupt low low_interrupt_service_routine save=PRGD
```

In addition to file registers, entire data sections can also be named in the `save=` clause. For example, to save a user-defined section named `mydata`, the following pragma directive would be used:

```
#pragma interrupt high_interrupt_service_routine save=section("mydata")
```

If an interrupt service routine calls another function, the normal functions' temporary data section (which is named `.tmpdata`) should be saved using a `save=section(".tmpdata")` qualifier on the interrupt pragma command. For example:

```
#pragma interrupt high_interrupt_service_routine save=section(".tmpdata")
```

If an interrupt service routine uses math library functions or calls a function that returns 24- or 32-bit data, the math data section (which is named `MATH_DATA`) should be saved using a `save=section("MATH_DATA")` qualifier on the interrupt pragma command. For example:

```
#pragma interrupt high_interrupt_service_routine save=section("MATH_DATA")
```

2.9.2.5 LATENCY

The time between when an interrupt occurs and when the first ISR instruction is executed is the latency of the interrupt. The three elements that affect latency are:

1. **Processor servicing of interrupt**: The amount of time it takes the processor to recognize the interrupt and branch to the first address of the interrupt vector. To determine this value refer to the processor data sheet for the specific processor and interrupt source being used.

2. **Interrupt vector execution**: The amount of time it takes to execute the code at the interrupt vector that branches to the ISR.

3. **ISR prologue code**: The amount of time it takes MPLAB C18 to save the compiler managed resources and the data in the `save=` list.

2.9.2.6 NESTING INTERRUPTS

Low-priority interrupts may be nested since active registers are saved onto the software stack. Only a single instance of a high-priority interrupt service routine may be active at a time since these ISR’s use the single-level hardware shadow registers.

If nesting of low-priority interrupts is desired, a statement to set the `GIEL` bit can be added near the beginning of the ISR. See the processor data sheet for details.

```
Note: If an ISR calls a function that returns a value less than or equal to 32 bits in size, the locations associated with the return value (see 3.2.1 “Return Values”) should be specified in the `save=` list of the interrupt pragma.
```
2.9.3  

#pragma varlocate bank variable-name
#pragma varlocate section-name variable-name

The `varlocate` pragma tells the compiler where a variable will be located at link time, enabling the compiler to perform more efficient bank switching.

The `varlocate` specifications are not enforced by the compiler or linker. The sections that contain the variables should be assigned to the correct bank explicitly in the linker script or via absolute sections in the module(s) where they are defined.

2.9.3.1  SYNTAX

`variable-locate-directive :
    # pragma varlocate bank variable-name[ , variable-name...]
    | # pragma varlocate section-name variable-name[ , variable-name...]

bank : integer constant
variable-name : C identifier
section-name : C identifier

2.9.3.2  EXAMPLE

For example, in one file, `c1` and `c2` are explicitly assigned to bank 1.

```c
#pragma udata bank1=0x100
signed char c1;
signed char c2;
```

In a second file, the compiler is told that both `c1` and `c2` are located in bank 1.

```c
#pragma varlocate 1 c1
extern signed char c1;

#pragma varlocate 1 c2
extern signed char c2;
```

```c
void main (void)
{
    c1 += 5;
    /* No MOVLB instruction needs to be generated here. */
    c2 += 5;
}
```

When `c1` and `c2` are used in the second file, the compiler knows that both variables are in the same bank and does not need to generate a second `MOVLB` instruction when using `c2` immediately after `c1`.
2.10  PROCESSOR-SPECIFIC HEADER FILES

The processor-specific header file is a C file that contains external declarations for the special function registers, which are defined in the register definitions file (see 2.11 “Processor-Specific Register Definitions Files”). For example, in the PIC18C452 processor-specific header file, PORTA is declared as:

```c
extern volatile near unsigned char PORTA;
```

and as:

```c
extern volatile near union {
    struct {
        unsigned RA0:1;
        unsigned RA1:1;
        unsigned RA2:1;
        unsigned RA3:1;
        unsigned RA4:1;
        unsigned RA5:1;
        unsigned RA6:1;
    };
    struct {
        unsigned AN0:1;
        unsigned AN1:1;
        unsigned AN2:1;
        unsigned AN3:1;
        unsigned T0CKI:1;
        unsigned SS:1;
        unsigned OSC2:1;
    };
    struct {
        unsigned :2;
        unsigned VREFM:1;
        unsigned VREFP:1;
        unsigned :1;
        unsigned AN4:1;
        unsigned CLKOUT:1;
    };
    struct {
        unsigned :5;
        unsigned LVDIN:1;
    };
} PORTAbits;
```

The first declaration specifies that `PORTA` is a byte (`unsigned char`). The `extern` modifier is needed since the variables are declared in the register definitions file. The `volatile` modifier tells the compiler that it cannot assume that `PORTA` retains values assigned to it. The `near` modifier specifies that the port is located in access RAM.

The second declaration specifies that `PORTAbits` is a union of bit-addressable anonymous structures (see 2.8.1 “Anonymous Structures”). Since individual bits in a special function register may have more than one function (and hence more than one name), there are multiple structure definitions inside the union all referring to the same register. Respective bits in all structure definitions refer to the same bit in the register. Where a bit has only one function for its position, it is simply padded in other structure definitions. For example, bits 1 and 2 on `PORTA` are simply padded in the third and fourth structures because they only have two names, whereas, bit 6 has four names and is specified in each of the structures.
Any of the following statements can be written to use the PORTA special function register:

```c
PORTA = 0x34; /* Assigns the value 0x34 to the port */
PORTAbits.AN0 = 1; /* Sets the AN0 pin high */
PORTAbits.RA0 = 1; /* Sets the RA0 pin high, same as above statement */
```

In addition to register declarations, the processor-specific header file defines inline assembly macros. These macros represent certain PICmicro MCU instructions that an application may need to execute from C code. Although, these instructions could be included as inline assembly instructions, as a convenience they are provided as C macros (see Table 2-8).

In order to use the processor-specific header file, choose the header file that pertains to the device being used (e.g., if using a PIC18C452, #include <p18c452.h> in the application source code). The processor-specific header files are located in the c:\mcc18\ directory, where c:\mcc18 is the directory where the compiler is installed. Alternatively, #include <p18cxxx.h> will include the proper processor-specific header file based on the processor selected on the command line via the -p command-line option.

**TABLE 2-8: C MACROS PROVIDED FOR PICmicro MCU INSTRUCTIONS**

<table>
<thead>
<tr>
<th>Instruction Macro</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nop()</td>
<td>Executes a no operation (NOP)</td>
</tr>
<tr>
<td>Clrwdt()</td>
<td>Clears the watchdog timer (CLRWDT)</td>
</tr>
<tr>
<td>Sleep()</td>
<td>Executes a SLEEP instruction</td>
</tr>
<tr>
<td>Reset()</td>
<td>Executes a device reset (RESET)</td>
</tr>
<tr>
<td>Rlcf(var, dest, access)</td>
<td>Rotates var to the left through the carry bit.</td>
</tr>
<tr>
<td>Rlncf(var, dest, access)</td>
<td>Rotates var to the left without going through the carry bit</td>
</tr>
<tr>
<td>Rrcf(var, dest, access)</td>
<td>Rotates var to the right through the carry bit</td>
</tr>
<tr>
<td>Rrncf(var, dest, access)</td>
<td>Rotates var to the right without going through the carry bit</td>
</tr>
<tr>
<td>Swapf(var, dest, access)</td>
<td>Swaps the upper and lower nibble of var</td>
</tr>
</tbody>
</table>

**Note 1:** Using any of these macros in a function affects the ability of the MPLAB C18 compiler to perform optimizations on that function.

**Note 2:** var must be an 8-bit quantity (i.e., char) and not located on the stack.

**Note 3:** If dest is 0, the result is stored in WREG, and if dest is 1, the result is stored in var. If access is 0, the access bank will be selected, overriding the BSR value. If access is 1, then the bank will be selected as per the BSR value.
2.11 PROCESSOR-SPECIFIC REGISTER DEFINITIONS FILES

The processor-specific register definitions file is an assembly file that contains definitions for all the special function registers on a given device. The processor-specific register definitions file, when compiled, will become an object file that will need to be linked with the application (e.g., p18c452.asm compiles to p18c452.o). This object file is contained in p18xxxx.lib (e.g., p18c452.o is contained in p18c452.lib).

The source code for the processor-specific register definitions files is found in the c:\mcc18\src\proc directory and compiled object code is found in the c:\mcc18\lib directory, where c:\mcc18 is the directory where the compiler is installed.

For example, PORTA is defined in the PIC18C452 processor-specific register definitions file as:

```
SFR_UNBANKED0 UDATA_ACS H'f80'
PORTA
PORTAbits RES 1 ; 0xf80
```

The first line specifies the file register bank where PORTA is located and the starting address for that bank. PORTA has two labels, PORTAbits and PORTA, both referring to the same location (in this case 0xf80).

2.12 CONFIGURATION WORDS

The default linker script for each part contains a section named CONFIG. For example, the p18c452.lkr script contains the following statements:

```
CODEPAGE NAME=config START=0x300000 END=0x300007 PROTECTED
...
SECTION NAME=CONFIG ROM=config
```

The #pragma romdata CONFIG directive is used to set the current romdata section to the section named CONFIG. Each configuration word can be set up (in order) using initialized rom unsigned integers. For example:

```
#pragma romdata CONFIG
rom const unsigned int config_word1 = 0x0023;
rom const unsigned int config_word2 = 0x0004;
```

will set the bits in the first two configuration words.
Chapter 3. Runtime Model

This section discusses the runtime model or the set of assumptions that the MPLAB C18 compiler operates, including information about how the MPLAB C18 compiler uses the resources of the PIC18 PICmicro microcontrollers.

3.1 MEMORY MODELS

MPLAB C18 provides full library support for both a small and a large memory model (see Table 3-1). The small memory model is selected using the -ms command-line option and the large memory model using the -ml option. If neither is provided, the small memory model is used by default.

<table>
<thead>
<tr>
<th>Memory Model</th>
<th>Command-line Switch</th>
<th>Default ROM Range Qualifier</th>
<th>Size of Pointers to Program Space</th>
</tr>
</thead>
<tbody>
<tr>
<td>small</td>
<td>-ms</td>
<td>near</td>
<td>16 bits</td>
</tr>
<tr>
<td>large</td>
<td>-ml</td>
<td>far</td>
<td>24 bits</td>
</tr>
</tbody>
</table>

The difference between the small and large models is the size of pointers that point to program memory. In the small memory model, both function and data pointers that point to program memory use 16 bits. This has the effect of restricting pointers to addressing only the first 64k of program memory in the small model. In the large memory model, 24 bits are used. Applications using more than 64k of program memory must use the large memory model.

The memory model setting can be overridden on a case-by-case basis by using the near or far qualifier when declaring a pointer into program space. Pointers to near memory use 16 bits as in the small memory model, and pointers to far memory use 24 bits as in the large memory model.

The following example creates a pointer to program memory that can address up to and beyond 64k of program memory space, even when the small memory model is being used\(^1\):

```c
far rom *pgm_ptr;
```

The following example creates a function pointer that can address up to and beyond 64k of program memory space, even when the small memory model is being used\(^2\):

```c
far rom void (*fp) (void);
```

If the same memory model is not used for all files in a project, all global pointers to program memory should be declared with explicit near or far qualifiers so that they are accessed correctly in all modules. The pre-compiled libraries distributed with MPLAB C18 can be used with either the small or large memory models.

---

1. Following the use of a far data pointer in a small memory model program, the TBLPTRU byte must be cleared by the user. MPLAB C18 does not clear this byte.
2. Following the use of a far function pointer in a small memory model program, the PCLATU byte must be cleared by the user. MPLAB C18 does not clear this byte.
3.2 CALLING CONVENTIONS

The MPLAB C18 software stack is an upward growing stack data structure on which the compiler places function arguments and local variables that have the storage class `auto`. The software stack is distinct from the hardware stack upon which the PICmicro microcontroller places function call return addresses. Figure 3-1 shows an example of the software stack.

**FIGURE 3-1: EXAMPLE OF SOFTWARE STACK**

The stack pointer (FSR1) always points to the next available stack location. MPLAB C18 uses FSR2 as the frame pointer, providing quick access to local variables and parameters. When a function is invoked, its stack-based arguments are pushed onto the stack in right-to-left order and the function is called. The leftmost function argument is on the top of the software stack upon entry into the function.

Figure 3-2 shows the software stack immediately prior to a function call.

**FIGURE 3-2: EXAMPLE OF SOFTWARE STACK IMMEDIATELY PRIOR TO FUNCTION CALL**

The frame pointer references the location on the stack that separates the stack-based arguments from the stack-based local variables. Stack-based arguments are located at negative offsets from the frame pointer, and stack based local variables are located at positive offsets from the frame pointer. Immediately upon entry into a C function, the called function pushes the value of FSR2 onto the stack and copies the value of FSR1 into FSR2, thereby saving the context of the calling function and initializing the frame pointer of the current function. Then the total size of stack-based local variables for the function is added to the stack pointer, allocating stack space for those variables. References to stack-based local variables and stack-based arguments are resolved according to offsets from the frame pointer. Figure 3-3 shows a software stack following a call to a C function.
3.2.1 Return Values

The location of the return value is dependent on the size of the return value. Table 3-2 details the location of the return value based on its size.

TABLE 3-2: RETURN VALUES

<table>
<thead>
<tr>
<th>Return Value Size</th>
<th>Return Value Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>8 bits</td>
<td>WREG</td>
</tr>
<tr>
<td>16 bits</td>
<td>PRODH:PRODL</td>
</tr>
<tr>
<td>24 bits</td>
<td>(AARGB2+2):(AARGB2+1):AARGB2</td>
</tr>
<tr>
<td>32 bits</td>
<td>(AARGB3+3):(AARGB3+2):(AARGB3+1):AARGB3</td>
</tr>
<tr>
<td>&gt; 32 bits</td>
<td>on the stack, and FSR0 points to the return value</td>
</tr>
</tbody>
</table>
3.2.2 Managing the Software Stack

The stack is sized and placed via the linker script with the `STACK` directive. The `STACK` directive has two arguments: `SIZE` and `RAM` to control the allocated stack size and its location, respectively. For example, to allocate a 128 byte stack and place that stack in the memory region `gpr3`:

```
STACK SIZE=0x80 RAM=gpr3
```

MPLAB C18 supports stack sizes greater than 256 bytes. The default linker scripts allocate one memory region per bank of memory, so to allocate a stack larger than 256 bytes requires combining two or more memory regions, as the stack section cannot cross memory region boundaries. For example, the default linker script for the PIC18C452 contains the definitions:

```
DATABANK NAME=gpr4 START=0x400 END=0x4ff
DATABANK NAME=gpr5 START=0x500 END=0x5ff
...
STACK SIZE=0x100 RAM=gpr5
```

To allocate a 512 byte stack in banks 4 and 5, these definitions should be replaced with:

```
DATABANK NAME=stackregion START=0x400 END=0x5ff PROTECTED
STACK SIZE=0x200 RAM=stackregion
```

If a stack larger than 256 bytes is used, the `-ls` option must be given to the compiler. There is a slight performance penalty that is incurred when using a large stack, as both bytes of the frame pointer (`FSR2L` and `FSR2H`) must be incremented/decremented when doing a push/pop, rather than just the low-byte.

The size of the software stack required by an application varies with the complexity of the program. When nesting function calls, all `auto` parameters and variables of the calling function will remain on the stack. Therefore, the stack must be large enough to accommodate the requirements by all functions in a tree.

MPLAB C18 supports parameters and local variables allocated either on the software stack or directly from global memory. The `static` keyword places a local variable or a function parameter in global memory instead of on the software stack. In general, stack-based local variables and function parameters require more code to access than `static` local variables and function parameters (see 2.3.2 "static Function Arguments"). Functions that use stack-based variables are more flexible in that they can be reentrant and/or recursive.

3.2.3 Mixing C and Assembly

3.2.3.1 CALLING C FUNCTIONS FROM ASSEMBLY

When calling C functions from assembly:

- C functions are inherently global, unless defined as `static`.
- The C function name must be declared as an `extern` symbol in the assembly file.
- A `CALL` or an `RCALL` must be used to make the function call.
3.2.3.1.1 auto Parameters

auto parameters are pushed onto the software stack from right to left. For multi-byte data, the low byte is pushed onto the software stack first.

EXAMPLE 3-1:

Given the following prototype for a C function:

```c
char add (auto char x, auto char y);
```

to call the function `add` with values `x = 0x61` and `y = 0x65`, the value for `y` must be pushed onto the software stack followed by the value of `x`. The return value, since it is 8 bits, will be returned in `WREG` (see Table 3-2), i.e.,

```c
EXTERN add  ; defined in C module
...
MOVLW 0x65
MOVWF POSTINC1 ; y = 0x65 pushed onto stack
MOVLW 0x61
MOVWF POSTINC1 ; x = 0x61 pushed onto stack
CALL  add
MOVWF result  ; result is returned in WREG
...
```

EXAMPLE 3-2:

Given the following prototype for a C function:

```c
int sub (auto int x, auto int y);
```

to call the function `sub` with values `x = 0x7861` and `y = 0x1265`, the value for `y` must be pushed onto the software stack followed by the value of `x`. The return value, since it is 16 bits, will be returned in `PRODH:PRODL` (see Table 3-2), i.e.,

```c
EXTERN sub  ; defined in C module
...
MOVLW 0x65
MOVWF POSTINC1
MOVLW 0x12
MOVWF POSTINC1        ; y = 0x1265 pushed onto stack
MOVLW 0x61
MOVWF POSTINC1
MOVLW 0x78
MOVWF POSTINC1        ; x = 0x7861 pushed onto stack
CALL  sub
MOVFF PRODL, result
MOVFF PRODH, result+1 ; result is returned in PRODH:PRODL
...
```
3.2.3.1.2 static Parameters

Static parameters are allocated globally, enabling direct access. The naming convention for static parameters is __function_name:n, where function_name is replaced by the name of the function and n is the parameter position, with numbering starting from 0. For example, given the following prototype for a C function:

```c
char add (static char x, static char y);
```

the value for y is accessed by using __add:1, and the value of x is accessed by using __add:0.

**Note:** Since ':' is not a valid character in the MPASM assembler’s labels, accessing static parameters in assembly functions is not supported.

3.2.3.2 CALLING ASSEMBLY FUNCTIONS FROM C

When calling assembly functions from C:

- The function label must be declared as global in the ASM module.
- The function must be declared as extern in the C module.
- The function must maintain the MPLAB C18 compiler’s runtime model (e.g., return values must be returned in the locations specified in Table 3-2).
- The function is called from C using standard C function notation.

**EXAMPLE 3-3:**

Given the following function written in assembly:

```assembly
UDATA_ACS
delay_temp   RES     1

CODE
asm_delay
    SETF   delay_temp
not_done
    DECF   delay_temp
    BNZ    not_done
done
    RETURN

GLOBAL asm_delay  ; export so linker can see it
END
```

To call the function `asm_delay` from a C source file, an external prototype for the assembly function must be added, and the function called using standard C function notation:

```c
/* asm_delay is found in an assembly file */
extern void asm_delay (void);

void main (void)
{
    asm_delay ();
}
```
EXAMPLE 3-4:

Given the following function written in assembly,

```assembly
INCLUDE "p18c452.inc"

CODE
asm_timed_delay
not_done

; Figure 3-2 is what the stack looks like upon
; entry to this function.
;
; ‘time’ is passed on the stack and must be >= 0
MOVLW 0xff
DECF PLUSW1, 0x1, 0x0
BNZ not_done
done

RETURN
; export so linker can see it
GLOBAL asm_timed_delay
END
```

to call the function `asm_timed_delay` from a C source file, an external prototype for the assembly function must be added, and the function called using standard C function notation:

```c
/* asm_timed_delay is found in an assembly file */
extern void asm_timed_delay (unsigned char);

void main (void)
{
    asm_timed_delay (0x80);
}
```

### 3.2.3.3 USING C VARIABLES IN ASSEMBLY

When using C variables in assembly:

- The C variable must have global scope in the C source file.
- The C variable must be declared as an `extern` symbol in the assembly file.
EXAMPLE 3-5:

Given the following written in C:

```c
unsigned int c_variable;
void main (void)
{
    ...
}
```

to modify the variable `c_variable` from assembly, an external declaration must be added for the variable in the assembly source file:

```c
EXTERN c_variable  ; defined in C module
MYCODE CODE
asm_function
    MOVFW c_variable
    MOVWF c_variable+1
    done
    RETURN

; export so linker can see it
GLOBAL asm_function
END
```

3.2.3.4 USING ASSEMBLY VARIABLES IN C

When using assembly variables in C:

- The variable must be declared as `global` in the ASM module.
- The variable must be declared as `extern` in the C module.

EXAMPLE 3-6:

Given the following written in assembly,

```asm
MYDATA UDATA
asm_variable RES   2 ; 2 byte variable

; export so linker can see it
GLOBAL asm_variable
END
```

to change the variable `asm_variable` from a C source file, an external declaration must be added for the variable in the C source file. The variable can be used as if it were a C variable:

```c
extern unsigned int asm_variable;

void change_asm_variable (void)
{
    asm_variable = 0x1234;
}
```
3.3 STARTUP CODE

3.3.1 Default Behavior

The MPLAB C18 startup begins at the reset vector (address 0). The reset vector jumps to a function that initializes FSR1 and FSR2 to reference the software stack, optionally calls a function to initialize iData sections (data memory initialized data) from program memory, and loops on a call to the application’s main() function.

Whether the startup code initializes iData sections is determined by which startup code module is linked with the application. The c018i.o module performs the initialization, while the c018.o module does not. The default linker scripts provided by MPLAB C18 link with c018i.o.

The ANSI standard requires that all objects with static storage duration that are not initialized explicitly are set to zero. With both the c018.o and c018i.o startup code modules, this requirement is not met. A third startup module, c018iz.o, is provided to meet this requirement. If this startup code module is linked with the application, then, in addition to initializing iData sections, all objects with static storage duration that are not initialized explicitly are set to zero.

To perform initialization of data memory, the MPLINK linker creates a copy of initialized data memory in program memory that the startup copies to data memory. The .cinit section is populated by the MPLINK linker to describe where the program memory images should be copied to. Table 3-3 describes the format of the .cinit section.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_init</td>
<td>Number of sections</td>
<td>16 bit</td>
</tr>
<tr>
<td>from_addr_0</td>
<td>Program memory start address of section 0</td>
<td>32 bit</td>
</tr>
<tr>
<td>to_addr_0</td>
<td>Data memory start address of section 0</td>
<td>32 bit</td>
</tr>
<tr>
<td>size_0</td>
<td>Number of data memory bytes to initialize for section 0</td>
<td>32 bit</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>from_addr_n</td>
<td>Program memory start address of section n</td>
<td>32 bit</td>
</tr>
<tr>
<td>to_addr_n</td>
<td>Data memory start address of section n</td>
<td>32 bit</td>
</tr>
<tr>
<td>size_n</td>
<td>Number of data memory bytes to initialize for section n</td>
<td>32 bit</td>
</tr>
</tbody>
</table>

Note 1: \( n = \text{num\_init} - 1 \)

After the startup code sets up the stack and optionally copies initialized data, it calls the main() function of the C program. There are no arguments passed to main(). MPLAB C18 transfers control to main() via a looped call, i.e.:

```c
loop:
    // Call the user's main routine
    main();
    goto loop;
```
3.3.2 Customization

To execute application-specific code immediately after a device reset but before any other code generated by the compiler is executed, edit the desired startup file and add the code to the beginning of the _entry() function.

To customize the startup files:
1. Go to the c:\mcc18\src\startup directory, where c:\mcc18 is the directory where the compiler is installed.
2. Edit either c018.c, c018i.c or c018iz.c to add any customized startup code desired.
3. Compile the updated startup file to generate either c018.o, c018i.o or c018iz.o.

3.4 COMPILER-MANAGED RESOURCES

Certain special function registers and data sections of the PIC18 PICmicro microcontrollers are used by MPLAB C18 and are not available for general purpose user code. Table 3-4 indicates each of these resources, their primary use by the compiler, and whether the compiler automatically saves the resource when entering an ISR.

TABLE 3-4: COMPILER RESERVED RESOURCES

<table>
<thead>
<tr>
<th>Compiler-Managed Resource</th>
<th>Primary Use(s)</th>
<th>Automatically Saved</th>
</tr>
</thead>
<tbody>
<tr>
<td>PC</td>
<td>execution control</td>
<td>✓</td>
</tr>
<tr>
<td>WREG</td>
<td>intermediate calculations</td>
<td>✓</td>
</tr>
<tr>
<td>STATUS</td>
<td>calculation results</td>
<td>✓</td>
</tr>
<tr>
<td>BSR</td>
<td>bank selection</td>
<td>✓</td>
</tr>
<tr>
<td>PROD</td>
<td>multiplication results, return values, intermediate calculations</td>
<td>✓</td>
</tr>
<tr>
<td>section.tmpdata</td>
<td>intermediate calculations</td>
<td>✓</td>
</tr>
<tr>
<td>FSR0</td>
<td>pointers to RAM</td>
<td>✓</td>
</tr>
<tr>
<td>FSR1</td>
<td>stack pointer</td>
<td>✓</td>
</tr>
<tr>
<td>FSR2</td>
<td>frame pointer</td>
<td>✓</td>
</tr>
<tr>

</tr>
<tr>
<td>TABLAT</td>
<td>accessing values in program memory</td>
<td>✓</td>
</tr>
<tr>
<td>section MATH_DATA</td>
<td>arguments, return values and temporary locations for math library functions</td>
<td>✓</td>
</tr>
</tbody>
</table>

Note: Compiler temporary variables are placed in an access qualified udata section named .tmpdata. Interrupt service routines each create a separate section for temporary data storage (see 2.9.2 "#pragma interruptlow fname #pragma interrupt fname").
Chapter 4. Optimizations

The MPLAB C18 compiler is an optimizing compiler. It performs optimizations that are primarily intended to reduce code size. All of the optimizations that can be performed by the MPLAB C18 compiler are enabled by default, but can be completely disabled using the \texttt{-O-} command-line option. The MPLAB C18 compiler also allows optimizations to be enable or disable on a case-by-case basis. Table 4-1 outlines each of the optimizations that can be performed by the MPLAB C18 compiler, including the command-line option to enable or disable it, whether or not it affects debugging, and the section where it is discussed.

\begin{table}[h]
\centering
\begin{tabular}{|l|c|c|c|}
\hline
Optimization & To Enable & To Disable & Affects Debugging & Section \\
\hline
Duplicate String Merging & \texttt{-Om+} & \texttt{-Om-} & & 4.1 \\
Branches & \texttt{-Ob+} & \texttt{-Ob-} & & 4.2 \\
Banking & \texttt{-On+} & \texttt{-On-} & & 4.3 \\
WREG Content Tracking & \texttt{-Ow+} & \texttt{-Ow-} & & 4.4 \\
Code Straightening & \texttt{-Os+} & \texttt{-Os-} & & 4.5 \\
Tail Merging & \texttt{-Ot+} & \texttt{-Ot-} & & 4.6 \\
Unreachable Code Removal & \texttt{-Ou+} & \texttt{-Ou-} & & 4.7 \\
Copy Propagation & \texttt{-Op+} & \texttt{-Op-} & & 4.8 \\
Redundant Store Removal & \texttt{-Or+} & \texttt{-Or-} & & 4.9 \\
Dead Code Removal & \texttt{-Od+} & \texttt{-Od-} & & 4.10 \\
Procedural Abstraction & \texttt{-Opa+} & \texttt{-Opa-} & & 4.11 \\
\hline
\end{tabular}
\end{table}

\subsection{4.1 DUPLICATE STRING MERGING \quad \texttt{-Om+} / \texttt{-Om-}}

Duplicate string merging, when enabled, will take two or more identical literal strings and combine them into a single string table entry with a single instance of the raw data stored in program memory. For example, given the following, when duplicate string merging is enabled (\texttt{-Om+}), only a single instance of the data for the string “foo” would be stored in the output object file, and both \texttt{a} and \texttt{b} would reference this data.

\begin{verbatim}
cost rom char * a = “foo”;
cost rom char * b = “foo”;
\end{verbatim}

The \texttt{-Om-} command-line option disables duplicate string merging.
Duplicate string merging should not affect the ability to debug source code.
4.2 BRANCHES

The following branch optimizations are performed by the MPLAB C18 compiler when the -Ob+ command-line option is specified:

1. A branch (conditional or unconditional) to an unconditional branch can be modified to target the latter's target instead.
2. An unconditional branch to a RETURN instruction can be replaced by a RETURN instruction.
3. A branch (conditional or unconditional) to the instruction immediately following the branch can be removed.
4. A conditional branch to a conditional branch can be modified to target the latter's target if both branches branch on the same condition.
5. A conditional branch immediately followed by an unconditional branch to the same destination can be removed (i.e., the unconditional branch is sufficient).

The -Ob- command-line option disables branch optimizations.

Some of the branch optimizations save program space, while others may expose unreachable code, which can be removed by Unreachable Code Removal (see 4.7 "Unreachable Code Removal"). Branch optimization should not affect the ability to debug source code.

4.3 BANKING

Banking optimization removes MOVLB instruction in instances where it can be determined that the bank select register already contains the correct value. For example, given the following C source code fragment:

```c
unsigned char a, b;
    a = 5;
    b = 5;
```

If compiled with banking optimization disabled (-On-), MPLAB C18 will load the bank register prior to each assignment:

```
0x000000 MOVLB a
0x000002 MOVLW 0x5
0x000004 MOVWF a,0x1
0x000006 MOVLB b
0x000008 MOVWF b,0x1
```

When this same code is compiled with banking optimization enabled (-On+), MPLAB C18 may be able to eliminate the second MOVLB instruction by determining that the value of the bank register will not change:

```
0x000000 MOVLB a
0x000002 MOVLW 0x5
0x000004 MOVWF a,0x1
0x000006 MOVWF b,0x1
```

The banking optimization should not affect the ability to debug source code.
## 4.4 WREG CONTENT TRACKING

- Ow+ / -Ow-

WREG content tracking removes MOVLW instructions in instances where it can be determined that the working register already contains the correct value. For example, given the following C source code fragment:

```c
unsigned char a, b;
a = 5;
b = 5;
```

If compiled with WREG content tracking disabled (-Ow-), MPLAB C18 will load a value of 5 into the working register prior to each assignment:

- 0x000000 MOVLW 0x5
- 0x000002 MOVWF a,0x1
- 0x000004 MOVLW 0x5
- 0x000006 MOVWF b,0x1

When this same code is compiled with WREG tracking enabled (-Ow+), MPLAB C18 may be able to eliminate the second MOVLW instruction by determining that the value of WREG must already be 5 at this point:

- 0x000000 MOVLW 0x5
- 0x000002 MOVWF a,0x1
- 0x000004 MOVWF b,0x1

WREG content tracking should not affect the ability to debug source code.

## 4.5 CODE STRAIGHTENING

- Os+ / -Os-

Code straightening attempts to reorder code sequences so that they appear in the order in which they will be executed. This can move or remove branching instructions so that code may be smaller and more efficient. An example where this may occur in C is:

```c
first:
    sub1();
goto second;
third:
    sub3();
goto fourth;
second:
    sub2();
goto third;
fourth:
    sub4();
```

In this example, the function calls will occur in numerical order, namely: sub1, sub2, sub3 and then sub4. With code straightening disabled (-Os-), the original flow of the code is mirrored in the generated assembly code:

- 0x000000 first CALL sub1,0x0
- 0x000002
- 0x000004 BRA second
- 0x000006 third CALL sub3,0x0
- 0x000008
- 0x00000a BRA fourth
- 0x00000c second CALL sub2,0x0
- 0x00000e
- 0x000010 BRA third
- 0x000012 fourth CALL sub4,0x0
- 0x000014
With code straightening enabled (-Os+), the code is reordered sequentially, removing the branching instructions:

0x000000 first CALL sub1,0x0
0x000002
0x000004 second CALL sub2,0x0
0x000006
0x000008 third CALL sub3,0x0
0x00000a fourth CALL sub4,0x0
0x00000c

Code straightening should not affect the ability to debug source code.

4.6 TAIL MERGING

Tail merging attempts to combine multiple sequences of identical instructions into a single sequence. For example, given the following C source code fragment:

```c
if ( user_value )
    PORTB = 0x55;
else
    PORTB = 0x80
```

When compiled with tail merging disabled (-Ot-), a MOVWF PORTB,0x0 is generated in both cases of the if statement:

0x000000 MOVF user_value,0x0,0x0
0x000002 BZ 0xa
0x000004 MOVWF PORTB,0x0
0x000006 BRA 0xe
0x00000c MOVWF PORTB,0x0
0x00000e RETURN 0x0

However, when compiled with tail merging enabled (-Os+), only a single MOVWF PORTB,0x0 is generated and is used by both the if and else portions of the code:

0x000000 MOVF user_value,0x0,0x0
0x000002 BZ 0x8
0x000004 MOVWF PORTB,0x0
0x000006 BRA 0xa
0x000008 MOVWF PORTB,0x0
0x00000c RETURN 0x0

When debugging source code compiled with this optimization enabled, the incorrect source line may be highlighted because two or more source lines may share a single sequence of assembly code, making it difficult for the debugger to identify which source line is being executed.
4.7  UNREACHABLE CODE REMOVAL  -Ou+ / -Ou-

Unreachable code will attempt to remove any code that can be provably demonstrated to not execute during normal program flow. An example where this may occur in C is:

```
if (1)
{
    x = 5;
}
else
{
    x = 6;
}
```

In this code it is obvious that the else portion of this code snippet can never be reached. With unreachable code disabled (-Ou-), the generated assembly code will include the instructions necessary to move 6 to x and the instruction to branch around these instructions:

```
0x000000 MOVLB x
0x000002 MOVLW 0x5
0x000004 BRA 0xa
0x000006 MOVLB x
0x000008 MOVLW 0x6
0x00000a MOVWF x,0x1
```

With unreachable code enabled (-Ou+), the generated assembly code will not include the instructions for the else:

```
0x000000 MOVLB x
0x000002 MOVLW 0x5
0x000004 MOVWF x,0x1
```

The unreachable code optimization may affect the ability to set breakpoints on certain lines of C source code.

4.8  COPY PROPAGATION  -Op+ / -Op-

Copy propagation is a transformation that, given an assignment \( x \leftarrow y \) for some variables \( x \) and \( y \), replaces later uses of \( x \) with uses of \( y \), as long as intervening instructions have not changed the value of either \( x \) or \( y \). This optimization by itself does not save any instructions, but enables dead code removal (see 4.10 “Dead Code Removal”). An example where this may occur in C is:

```
char c;
void foo (char a)
{
    char b;
    b = a;
    c = b;
}
```

With copy propagation disabled (-Op-), the original code is mirrored in the generated assembly code:

```
0x000000 foo MOVFF a,b
0x000002
0x000004 MOVFF b,c
0x000006
0x000008 RETURN 0x0
```
With copy propagation enabled (-Op+), instead of \( b \) being moved to \( c \) for the second instruction, \( a \) is moved to \( c \):

\[
\begin{array}{ll}
0x000000 & \text{foo} \quad \text{MOVFF} \ a, b \\
0x000002 & \text{MOVFF} \ a, c \\
0x000004 & \text{MOVFF} \ a, c \\
0x000006 & \text{RETURN} \ 0x0
\end{array}
\]

Dead code removal would then delete the useless assignment of \( a \) to \( b \) (see 4.10 “Dead Code Removal”).

Copy propagation may affect the ability to debug source code.

4.9 REDUNDANT STORE REMOVAL

-Or+ / -Or-

When assignment of the form \( x \leftarrow y \) appears multiple times in an instruction sequence and the intervening code has not changed the value of \( x \) or \( y \), the second assignment may be removed. This is a special case of common subexpression elimination. An example where this may occur in C is:

```c
char c;
void foo (char a) {
    c = a;
    c = a;
}
```

With redundant store removal disabled (-Or-), the original code is mirrored in the generated assembly code:

\[
\begin{array}{ll}
0x000000 & \text{foo} \quad \text{MOVFF} \ a, c \\
0x000002 & \text{MOVFF} \ a, c \\
0x000004 & \text{MOVFF} \ a, c \\
0x000006 & \text{RETURN} \ 0x0
\end{array}
\]

With redundant store removal enabled (-Or+), the second assignment of \( c \) to \( a \) is not required:

\[
\begin{array}{ll}
0x000000 & \text{foo} \quad \text{MOVFF} \ a, c \\
0x000002 & \text{RETURN} \ 0x0
\end{array}
\]

Redundant store removal may affect the ability to set breakpoints on certain lines of C source code.

4.10 DEAD CODE REMOVAL

-Od+ / -Od-

Values computed in a function which are not used on any path to the function’s exit are considered dead. Instructions which compute only dead values are themselves considered dead. Values stored to locations visible outside the scope of the function are considered used (and therefore not dead) since it is not determinable whether the value is used or not. Using the same example as that shown in 4.8 “Copy Propagation”:

```c
char c;
void foo (char a) {
    char b;
    b = a;
    c = b;
}
```
With copy propagation enabled (-Op+) and dead code removal disabled (-Od-), the generated assembly code is that shown in 4.8 “Copy Propagation”:

```
0x000000 foo    MOVFF a,b
0x000002
0x000004        MOVFF b,c
0x000006
0x000008        RETURN 0x0
```

With copy propagation enabled (-Op+) and dead code removal enabled (-Od+), instead of b being moved to c for the second instruction, a is moved to c thus making the assignment to b dead and able to be removed:

```
0x000000 foo    MOVFF a,c
0x000002
0x000004        RETURN 0x0
```

The dead code removal optimization may affect the ability to set breakpoints on certain lines of C source code.

### 4.11 PROCEDURAL ABSTRACTION

-Opa+ / -Opa-

MPLAB C18, like most compilers, frequently generates code sequences that appear multiple times in a single object file. This optimization reduces the size of the generated code by creating a procedure containing the repeated code and replacing the copies with a call to the procedure. Procedural abstraction is performed across all functions in a given code section.

**Note:** Procedural abstraction generates a saving in program space at the potential expense of execution time.

For example, given the following C source code fragment:

```c
distance -= time * speed;
position += time * speed;
```

When compiled with procedural abstraction disabled (-Opa-), the code sequence generated for time * speed is generated for each instruction listed above. It is shown in bold below.

```
0x000000 main    MOVLB time
0x000002
0x000004        MOVF time,0x0,0x1
0x000006        MULWF speed,0x1
0x000008        MOVF PRODL,0x0,0x0
0x00000a        MOVWF PRODL,0x0
0x00000c        CLRF PRODL+1,0x0
0x00000e        SUBWF distance,0x1,0x1
0x000010        MOVF PRODL+1,0x0,0x0
0x000012        SUBWFB distance+1,0x1,0x1
0x000014        MOVF time,0x0,0x1
0x000016        MULWF speed,0x1
0x000018        MOVF PRODL,0x0,0x0
0x00001a        MOVWF PRODL,0x0
0x00001c        CLRF PRODL+1,0x0
0x00001e        MOVF WREG,0x0,0x0
0x000020        ADDWF position,0x1,0x1
0x000022        MOVF PRODL+1,0x0,0x0
0x000024        ADDWFC position+1,0x1,0x1
0x000026        RETURN 0x0
```

Note: Procedural abstraction generates a saving in program space at the potential expense of execution time.
Whereas, when compiled with procedural abstraction enabled (`-Opa+`), these two code sequences are abstracted into a procedure and the repeated code is replaced by a call to the procedure.

```
0x000000 main  MOVLB time
0x000002  CALL __pa_0,0x0
0x000004
0x000006  SUBWF distance,0x1,0x1
0x000008  MOVF PRODL+1,0x0,0x0
0x00000a  SUBWFB distance+1,0x1,0x1
0x00000c  CALL __pa_0,0x0
0x00000e
0x000010  ADDWF position,0x1,0x1
0x000012  MOVF PRODL+1,0x0,0x0
0x000014  ADDWFC position+1,0x1,0x1
0x000016  RETURN 0x0
0x000018  __pa_0  MOVF time,0x0,0x1
0x00001a  MULWF speed,0x1
0x00001c  MOVF PRODL,0x0,0x0
0x00001e  MOVWF PRODL,0x0
0x000020  CLR PRODL+1,0x0
0x000022  MOVF WREG,0x0,0x0
0x000024  RETURN 0x0
```

Not all matches are able to be abstracted in a single pass of procedural abstraction. Procedural abstraction is performed until no more abstractions occur or a maximum of four passes. The number of passes can be controlled via the `-pa=n` command-line option. Procedural abstraction can potentially add an additional $2^n - 1$ levels of function calls, where $n$ is the total number of passes. If the hardware stack is a limited resource in an application, the `-pa=n` command-line option can be used to adjust the number of times procedural abstraction is performed.

When debugging source code compiled with this optimization enabled, the incorrect source line may be highlighted because two or more source lines may share a single sequence of assembly code, making it difficult for the debugger to identify which source line is being executed.
Chapter 5. Sample Application

The following sample application will flash LEDs connected to PORTB of a PIC18C452 microcontroller. The command line used to build this application is:

```
mcc18 -p 18c452 -I c:\mcc18\h leds.c
```

where c:\mcc18 is the directory in which the compiler is installed. This sample application was designed for use with a PICDEM 2 demo board. This sample covers the following items:

1. Interrupt handling (#pragma interruptlow, interrupt vectors, interrupt service routines and context saving)
2. System header files
3. Processor-specific header files
4. #pragma sectiontype
5. Inline assembly
/* 1 */ #include <p18cxxx.h>
/* 2 */ #include <timers.h>
/* 3 */
/* 4 */ #define NUMBER_OF_LEDS 8
/* 5 */
/* 6 */ void timer_isr (void);
/* 7 */
/* 8 */ static unsigned char s_count = 0;
/* 9 */
/* 10 */ #pragma code low_vector=0x18
/* 11 */ void low_interrupt (void)
/* 12 */ {
/* 13 */   _asm GOTO timer_isr _endasm
/* 14 */ }
/* 15 */
/* 16 */ #pragma code
/* 17 */
/* 18 */ #pragma interruptlow timer_isr save=PROD
/* 19 */ void
/* 20 */ timer_isr (void)
/* 21 */ {
/* 22 */   static unsigned char led_display = 0;
/* 23 */
/* 24 */   INTCONbits.TMR0IF = 0;
/* 25 */
/* 26 */   s_count = s_count % (NUMBER_OF_LEDS + 1);
/* 27 */
/* 28 */   led_display = (1 << s_count++) - 1;
/* 29 */
/* 30 */   PORTB = led_display;
/* 31 */ }
/* 32 */
/* 33 */ void
/* 34 */ main (void)
/* 35 */ {
/* 36 */   TRISB = 0;
/* 37 */   PORTB = 0;
/* 38 */
/* 39 */   OpenTimer0 (TIMER_INT_ON & T0_SOURCE_INT & T0_16BIT);
/* 40 */   INTCONbits.GIE = 1;
/* 41 */
/* 42 */   while (1)
/* 43 */   {
/* 44 */     }
/* 45 */ }
Line 1: This line includes the generic processor header file. The correct processor is selected via the -p command-line option. (See 2.5.1 "System Header Files", 2.10 "Processor-Specific Header Files")

Line 10: For PIC18 devices, the low interrupt vector is found at 000000018h. This line of code changes the default code section to the absolute code section named low_vector located at address 0x18. (See 2.9.1 "#pragma sectiontype", 2.9.2.3 "Interrupt Vectors")

Line 13: This line contains inline assembly that will jump to the ISR. (See 2.8.2 "Inline Assembly", 2.9.2.3 "Interrupt Vectors")

Line 16: This line returns the compiler to the default code section. (See 2.9.1 "#pragma sectiontype", Table 2-7)

Line 18: This line specifies the function timer_isr as a low-priority interrupt service routine. This is required in order for the compiler to generate a RETFIE instruction instead of a RETURN instruction for the timer_isr function. In addition, it ensures that PROD special function register will be saved. (See 2.9.2 "#pragma interruptlow fname #pragma interruptfname", 2.9.2.4 "ISR Context Saving")

Line 19-20: These lines define the timer_isr function. Notice that it does not take any parameters, and does not return anything (as required by ISRs). (See 2.9.2.2 "Interrupt Service Routines")

Line 24: This line clears the TMR0 interrupt flag to stop the program from processing the same interrupt multiple times. (See 2.10 "Processor-Specific Header Files")

Line 30: This line demonstrates how to modify the special function register PORTB in C. (See 2.10 "Processor-Specific Header Files")

Line 36-37: These lines initialize the special function registers TRISB and PORTB. (See 2.10 "Processor-Specific Header Files")

Line 39: This line enables the TMR0 interrupt, setting up the timer as an internal 16-bit clock.

Line 40: This line enables global interrupts. (See 2.10 "Processor-Specific Header Files")
Appendix A. COFF File Format

The Microchip COFF specification is based upon the UNIX System V COFF format as described in *Understanding and Using COFF*, Gintaras R. Gircys © 1988, O’Reilly and Associates, Inc. Special mention is made where the Microchip format differs from that described there.

A.1 struct filehdr - FILE HEADER

The `filehdr` structure holds information regarding the file. It is the first entry in a COFF file. It is used to denote where the optional file header, symbol table and section headers begin.

```c
typedef struct filehdr
{
    unsigned short f_magic;
    unsigned short f_nscns;
    unsigned long f_timdat;
    unsigned long f_symptr;
    unsigned long f_nsyms;
    unsigned short f_opthdr;
    unsigned short f_flags;
} filehdr_t;
```

A.1.1 unsigned short f_magic

The magic number is used to identify the implementation of COFF that the file follows. For Microchip PICmicro COFF files, this number is 0x1234.

A.1.2 unsigned short f_nscns

The number of sections in the COFF file.

A.1.3 unsigned long f_timdat

The time and date stamp when the COFF file was created (this value is a count of the number of seconds since midnight January 1, 1970).

A.1.4 unsigned long f_symptr

A pointer to the symbol table.

A.1.5 unsigned long f_nsyms

The number of entries in the symbol table.

A.1.6 unsigned short f_opthdr

The size of the optional header record.
A.1.7 unsigned short f_flags

Information on what is contained in the COFF file. Table A-1 shows the different file header flags, along with a description and respective values.

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>F_RELFLG</td>
<td>Relocation information has been stripped from the COFF file.</td>
<td>0x0001</td>
</tr>
<tr>
<td>F_EXEC</td>
<td>The file is executable, and has no unresolved external symbols.</td>
<td>0x0002</td>
</tr>
<tr>
<td>F_LNNO</td>
<td>Line number information has been stripped from the COFF file.</td>
<td>0x0004</td>
</tr>
<tr>
<td>L_SYMS</td>
<td>Local symbols have been stripped from the COFF file.</td>
<td>0x0080</td>
</tr>
<tr>
<td>F_GENERIC</td>
<td>The COFF file is processor independent.</td>
<td>0x8000</td>
</tr>
</tbody>
</table>

A.2 struct opthdr - OPTIONAL FILE HEADER

The opthdr structure contains implementation dependent file level information. For Microchip PIC COFF files, it is used to specify the name of the target processor, version of the compiler/assembler, and to define relocation types.

Note that the layout of this header is specific to the implementation (i.e., the Microchip optional header is not the same format as the System V optional header).

typedef struct opthdr
{
    unsigned short magic;
    unsigned short vstamp;
    unsigned long proc_type;
    unsigned long rom_width_bits;
    unsigned long ram_width_bits;
} opthdr_t;

A.2.1 unsigned short magic

The magic number can be used to determine the appropriate layout.

A.2.2 unsigned short vstamp

Version stamp.
A.2.3 unsigned long proc_type

Target processor type. Table A-2 shows the processor type along with the associated value stored in this field.

<table>

<td>0xA422</td>
</tr>
</tbody>
</table>

A.2.4 unsigned long rom_width_bits

Width of program memory in bits.

A.2.5 unsigned long ram_width_bits

Width of data memory in bits.
A.3 struct scnhdr - SECTION HEADER

The scnhdr structure contains information related to an individual section. The Microchip PIC COFF files make a slight departure from the normal COFF definition of the section name. Since the Microchip PIC COFF section names may be longer than eight characters, the Microchip PIC COFF files allow a string table entry for long names.

typedef struct scnhdr
{
    union
    {
        char _s_name[8] /* section name is a string */
        struct
        {
            unsigned long _s_zeroes
            unsigned long _s_offset
        }_s_s;
    }_s;

    unsigned long s_paddr;
    unsigned long s_vaddr;
    unsigned long s_size;
    unsigned long s_scnptr;
    unsigned long s_relptr;
    unsigned long s_lnnoptr;
    unsigned short s_nreloc;
    unsigned short s_nlnno;
    unsigned long s_flags;
} scnhdr_t;

A.3.1 union _s

A string or a reference into the string table. Strings of fewer than eight characters are stored directly, and all others are stored in the string table. If the first four characters of the string are 0, then the last four bytes are assumed to be an offset into the string table. This is a bit nasty as it is not strictly conforming to the ANSI specification (i.e., type munging is undefined behavior by the standard), but it is effective and it maintains binary compatibility with the System V layout, which other options would not do. This implementation has the advantage of mirroring the standard System V structure used for long symbol names.

A.3.1.1 char s_name[8]

In-place section name. If the section name is fewer than eight characters long, then the section name is stored in place.

A.3.1.2 struct _s_s

Section name is stored in the string table. If the first four characters of the section name are zero, then the last four form an offset into the string table to find the name of the section.

A.3.1.2.1 unsigned long _s_zeroes

First four characters of the section name are zero.

A.3.1.2.2 unsigned long _s_offset

Offset of section name in the string table.
A.3.1.3 unsigned long s_paddr
Physical address of the section.

A.3.1.4 unsigned long s_vaddr
Virtual address of the section. Always contains the same value as s_paddr.

A.3.2 unsigned long s_size
Size of this section.

A.3.3 unsigned long s_scnptr
Pointer to the raw data in the COFF file for this section.

A.3.4 unsigned long s_relptra
Pointer to the relocation information in the COFF file for this section.

A.3.5 unsigned long s_lnnoptr
Pointer to the line number information in the COFF file for this section.

A.3.6 unsigned short s_nreloc
The number of relocation entries for this section.

A.3.7 unsigned short s_nlnno
The number of line number entries for this section.

A.3.8 unsigned long s_flags
Section type and content flags. The flags which define the section type and the section qualifiers are stored as bitfields in the s_flags field. Masks are defined for the bitfields to ease access. Table A-3 shows the different section header flags, along with a description and respective values.

**TABLE A-3: SECTION HEADER FLAGS**

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
<th>Value</th>

<tr>
<td>STYP_OVERLAY</td>
<td>Section is overlaid with other sections of the same name from different object modules.</td>
<td>0x04000</td>
</tr>
<tr>
<td>STYP_ACCESS</td>
<td>Section is available using access bit.</td>
<td>0x08000</td>
</tr>
<tr>
<td>STYP_ACTREC</td>
<td>Section contains the overlay activation record for a function.</td>
<td>0x10000</td>
</tr>
</tbody>
</table>
A.4 struct reloc - RELOCATION ENTRY

Any instruction that accesses a relocatable identifier (variable, function, etc.) must have a relocation entry. This differs from the System V relocation data, where the offset is stored in the location being relocated to, in that the offset to add to the base address of the symbol is stored in the relocation entry. This is necessary because Microchip relocations are not restricted to just filling in an address+offset value into the data stream, but also do simple code modifications. It is much more straightforward to store the offset here, at the cost of a slightly increased file size.

typedef struct reloc
{
    unsigned long r_vaddr;
    unsigned long r_symndx;
    short r_offset;
    unsigned short r_type;
} reloc_t;

A.4.1 unsigned long r_vaddr
Address of reference (byte offset relative to start of raw data).

A.4.2 unsigned long r_symndx
Index into symbol table.

A.4.3 short r_offset
Signed offset to be added to the address of symbol r_symndx.

A.4.4 unsigned short r_type
Relocation type, implementation defined values. Table A-4 lists the relocation types, along with a description and respective values.
### TABLE A-4: RELOCATION TYPES

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>RELOCT_CALL</td>
<td>CALL instruction (first word only on PIC18)</td>
<td>1</td>

<td>RELOCT_SCNEND_LFSR1</td>
<td>Address of the end of a section on LFSR</td>
<td>31</td>
</tr>
<tr>
<td>RELOCT_SCNEND_LFSR2</td>
<td></td>
<td>32</td>
</tr>
</tbody>
</table>
A.5 struct syment - SYMBOL TABLE ENTRY

Symbols are created for all identifiers, as well as sections, function begins, function ends, block begins and block ends.

#define SYMNMLEN 8
struct syment
{
  union
  {
    char _n_name[SYMNMLEN];
    struct
    {
      unsigned long _n_zeroes;
      unsigned long _n_offset;
    } _n_n;
    char * _n_nptr[2];
  } _n;
  unsigned long n_value;
  short n_scnum;
  unsigned short n_type;
  char n_sclass;
  char n_numaux;
}

A.5.1 union _n

The symbol name may be stored directly as a string, or it may be a reference to the string table. Symbol names of fewer than eight characters are stored here, with all others being stored in the string table. It is from this structure that the inspiration comes for extending the section data structures to allow for section names to be stored in the symbol table.

A.5.1.1 char _n_name [SYMNMLEN]

In-place symbol name, if fewer than eight characters long.

A.5.1.2 struct _n_n

Symbol name is located in string table. If the first four characters of the symbol name are zero, then the last four form an offset into the string table to find the name of the symbol.

A.5.1.2.1 unsigned long _n_zeroes

First four characters of the symbol name are zero.

A.5.1.2.2 unsigned long _n_offset

Offset of symbol name in the string table.

A.5.1.3 char * _n_nptr

Allows for overlaying.

A.5.2 unsigned long n_value

Value of symbol. Typically, this is the address of the symbol within the section in which it resides. For link-time constants (e.g., the Microchip symbol _stksize), the value is a literal value and not an address. To the linker, there is typically no difference. The distinction is only in the usage in the application code.
A.5.3 short n_scnum
References the section number where this symbol is located.

A.5.4 unsigned short n_type
Base type and derived type.

A.5.4.4 SYMBOL TYPES
Table A-5 lists the base types, along with a description and respective values.

**TABLE A-5: BASE SYMBOL TYPES**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>T_NULL</td>
<td>null</td>
<td>0</td>
</tr>
<tr>
<td>T_VOID</td>
<td>void</td>
<td>1</td>
</tr>
<tr>
<td>T_CHAR</td>
<td>character</td>
<td>2</td>
</tr>
<tr>
<td>T_SHORT</td>
<td>short integer</td>
<td>3</td>
</tr>
<tr>
<td>T_INT</td>
<td>integer</td>

<tr>
<td>C_ALIAS</td>
<td>Duplicate tag</td>
<td>105</td>
</tr>
<tr>
<td>C_HIDDEN</td>
<td>External symbol in dmert public library</td>
<td>106</td>
</tr>
<tr>
<td>C_EOF</td>
<td>End of file</td>
<td>107</td>
</tr>
<tr>
<td>C_LIST</td>
<td>Absolute listing on or off</td>
<td>108</td>
</tr>
<tr>
<td>C_SECTION</td>
<td>Section</td>
<td>109</td>
</tr>
</tbody>
</table>

**A.5.6 char n_numaux**

The number of auxiliary entries for this symbol.
A.6  **struct coff_lineno - LINE NUMBER ENTRY**

Any executable source line of code gets a `coff_lineno` entry in the line number table associated with its section. For a Microchip PIC COFF file, this means that every instruction may have a `coff_lineno` entry since the debug information is often for debugging through the absolute listing file. Readers of this information should note that the COFF file is not required to have an entry for every instruction, though it typically does. This information is significantly different from the System V format.

```c
struct coff_lineno
{
    unsigned long l_srcndx;
    unsigned short l_lnno;
    unsigned long l_paddr;
    unsigned short l_flags;
    unsigned long l_fcnndx;
} coff_lineno_t;
```

A.6.1  **unsigned long l_srcndx**

Symbol table index of associated source file.

A.6.2  **unsigned short l_lnno**

Line number.

A.6.3  **unsigned long l_paddr**

Address of code for this line number entry.

A.6.4  **unsigned short l_flags**

Bit flags for the line number entry. Table A-8 lists the bit flags, along with a description and respective values.

**TABLE A-8: LINE NUMBER ENTRY FLAGS**

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>LINENO_HASFCN</td>
<td>Set if l_fcnndx is valid</td>
<td>0x01</td>
</tr>
</tbody>
</table>

A.6.5  **unsigned long l_fcnndx**

Symbol table index of associated function (if there is one).

A.7  **struct aux_file - AUXILIARY SYMBOL TABLE ENTRY FOR A SOURCE FILE**

```c
typedef struct aux_file
{
    unsigned long x_offset;
    unsigned long x_incline;
    char _unused[10];
} aux_file_t;
```

A.7.1  **unsigned long x_offset**

String table offset for filename.

A.7.2  **unsigned long x_incline**

Line number at which this file was included. If 0, file was not included.
A.8  **struct aux_scn** - AUXILIARY SYMBOL TABLE ENTRY FOR A SECTION

```c
typedef struct aux_scn
{
    unsigned long x_scnlen;
    unsigned short x_nreloc;
    unsigned short x_nlinno;
    char _unused[10];
} aux_scn_t;
```

**A.8.1 unsigned long x_scnlen**
Section length.

**A.8.2 unsigned short x_nreloc**
Number of relocation entries.

**A.8.3 unsigned short x_nlinno**
Number of line numbers.

A.9  **struct aux_tag** - AUXILIARY SYMBOL TABLE ENTRY FOR A **struct/union/enum** TAGNAME

```c
typedef struct aux_tag
{
    char _unused[6];
    unsigned short x_size;
    char _unused2[4];
    unsigned long x_endndx;
    char _unused3[2];
} aux_tag_t;
```

**A.9.1 unsigned short x_size**
Size of **struct/union/enum**.

**A.9.2 unsigned long x_endndx**
Symbol index of next entry beyond this **struct/union/enum**.

A.10  **struct aux_eos** - AUXILIARY SYMBOL TABLE ENTRY FOR AN END OF **struct/union/enum**

```c
typedef struct aux_eos
{
    unsigned long x_tagndx;
    char _unused[2];
    unsigned short x_size;
    char _unused2[10];
} aux_eos_t;
```

**A.10.1 unsigned long x_tagndx**
Symbol index of a structure, union or enumerated tag.

**A.10.2 unsigned short x_size**
Size of a structure, union or enumeration.
A.11 struct aux_fcn - AUXILIARY SYMBOL TABLE ENTRY FOR A FUNCTION NAME

```c
typedef struct aux_fcn
{
    unsigned long x_tagndx;
    unsigned long x_size;
    unsigned long x_lnnoptr;
    unsigned long x_endndx;
    short x_actscnum;
} aux_fcn_t;
```

A.11.1 unsigned long x_lnnoptr
File pointer to line numbers for this function.

A.11.2 unsigned long x_endndx
Symbol index of next entry beyond this function.

A.11.3 short x_actscnum
Section number of the static activation record data.

A.12 struct aux_fcn_calls - AUXILIARY SYMBOL TABLE ENTRY FOR FUNCTION CALL REFERENCES

```c
typedef struct aux_fcn_calls
{
    unsigned long x_calleendx;
    unsigned long x_is_interrupt;
    char _unused[10];
} aux_fcn_calls_t;
```

A.12.1 unsigned long x_calleendx
Symbol index of the called function. If call of a higher order function, set to AUX_FCN_CALLS_HIGHERORDER.

```c
#define AUX_FCN_CALLS_HIGHERORDER ((unsigned long)-1)
```

A.12.2 unsigned long x_is_interrupt
Specifies whether the function is an interrupt, and if so, the priority of the interrupt.

- 0: not an interrupt
- 1: low priority
- 2: high priority
A.13 struct aux_arr - AUXILIARY SYMBOL TABLE ENTRY FOR AN ARRAY

```c
#define X_DIMNUM 4
typedef struct aux_arr
{
    unsigned long x_tagndx;
    unsigned short x_lnno;
    unsigned short x_size;
    unsigned short x_dimen[X_DIMNUM];
} aux_arr_t;
```

A.13.1 unsigned short x_size
Size of array.

A.13.2 unsigned short x_dimen[X_DIMNUM]
Size of first four dimensions.

A.14 struct aux_eobf - AUXILIARY SYMBOL TABLE ENTRY FOR THE END OF A BLOCK OR FUNCTION

```c
typedef struct aux_eobf
{
    char _unused[4];
    unsigned short x_lnno;
    char _unused2[12];
} aux_eobf_t;
```

A.14.1 unsigned short x_lnno
C source line number of the end, relative to start of block/function.

A.15 struct aux_bobf - AUXILIARY SYMBOL TABLE ENTRY FOR THE BEGINNING OF A BLOCK OR FUNCTION

```c
typedef struct aux_bobf
{
    char _unused[4];
    unsigned short x_lnno;
    char _unused2[6];
    unsigned long x_endndx;
    char _unused3[2];
} aux_bobf_t;
```

A.15.1 unsigned short x_lnno
C source line number of the beginning, relative to start enclosing scope.

A.15.2 unsigned long x_endndx
Symbol index of next entry past this block/function.
A.16 struct aux_var - AUXILIARY SYMBOL TABLE ENTRY FOR A VARIABLE OF TYPE struct/union/enum

    typedef struct aux_var
    {
        unsigned long x_tagndx;
        char _unused[2];
        unsigned short x_size;
        char _unused2[10];
    } aux_var_t;

A.16.1 unsigned long x_tagndx
Symbol index of a structure, union or enumerated tagname.

A.16.2 unsigned short x_size
Size of the structure, union or enumeration.
Appendix B. ANSI Implementation-Defined Behavior

B.1 INTRODUCTION

This section discusses MPLAB C18 implementation-defined behavior. The ISO standard for C requires that vendors document the specifics of “implementation-defined” features of the language.

Note: The section numbers in parenthesis, e.g., (6.1.2), refer to the ANSI C standard X3.159-1989.

Implementation-Defined Behavior for the following sections is covered in section G.3 of the ANSI C Standard.

B.2 IDENTIFIERS

ANSI C Standard: “The number of significant initial characters (beyond 31) in an identifier without external linkage (6.1.2).”
“The number of significant initial characters (beyond 6) in an identifier with external linkage (6.1.2).”
“Whether case distinctions are significant in an identifier with external linkage (6.1.2).”

Implementation: All MPLAB C18 identifiers have at least 31 significant characters. Case distinctions are significant in an identifier with external linkage.

B.3 CHARACTERS

ANSI C Standard: “The value of an integer character constant that contains more than one character or a wide character constant that contains more than one multibyte character (6.1.3.4).”

Implementation: The value of the integer character constant is the 8-bit value of the first character. Wide characters are not supported.

ANSI C Standard: “Whether a ‘plain’ char has the same range of values as signed char or unsigned char (6.2.1.1).”

Implementation: A plain char has the same range of values as a signed char. For MPLAB C18, this may be changed to unsigned char via a command line switch (-k).
B.4 INTEGERS

ANSI C Standard: “A char, a short int or an int bit-field, or their signed or unsigned varieties, or an enumeration type, may be used in an expression wherever an int or unsigned int may be used. If an int can represent all values of the original type, the value is converted to an int; otherwise, it is converted to an unsigned int. These are called the integral promotions. All other arithmetic types are unchanged by the integral promotions.

“The integral promotions preserve value including sign. (6.2.1.1).”

Implementation: MPLAB C18 does not enforce this by default. The -Oi option can be used to require the compiler to enforce the ANSI defined behavior. See 2.7.1 “Integer Promotions”.

ANSI C Standard: “The result of converting an integer to a shorter signed integer, or the result of converting an unsigned integer to a signed integer of equal length, if the value cannot be represented (6.2.1.2).”

Implementation: When converting from a larger integer type to a smaller integer type, the high order bits of the value are discarded and the remaining bits are interpreted according to the type of the smaller integer type. When converting from an unsigned integer to a signed integer of equal size, the bits of the unsigned integer are simply reinterpretated according to the rules for a signed integer of that size.

ANSI C Standard: “The results of bitwise operations on signed integers (6.3).”

Implementation: The bitwise operators are applied to the signed integer as if it were an unsigned integer of the same type (i.e., the sign bit is treated as any other bit).

ANSI C Standard: “The sign of the remainder on integer division (6.3.5).”

Implementation: The remainder has the same sign as the quotient.

ANSI C Standard: “The result of a right shift of a negative-valued signed integral type (6.3.7).”

Implementation: The value is shifted as if it were an unsigned integral type of the same size (i.e., the sign bit is not propagated).

B.5 FLOATING-POINT

ANSI C Standard: “The representations and sets of values of the various types of floating-point numbers (6.1.2.5).”

“The direction of truncation when an integral number is converted to a floating-point number that cannot exactly represent the original value (6.2.1.3).”

“The direction of truncation or rounding when a floating-point number is converted to a narrower floating-point number (6.2.1.4).”

Implementation: See 2.1.2 “Floating-Point Types”. The rounding to the nearest method is used.
B.6 ARRAYS AND POINTERS

ANSI C Standard: “The type of integer required to hold the maximum size of an array — that is, the type of the sizeof operator, size_t (6.3.3.4, 7.1.1).”

Implementation: size_t is defined as an unsigned short long int.

ANSI C Standard: “The result of casting a pointer to an integer or vice versa (6.3.4).”

Implementation: The integer will contain the binary value used to represent the pointer. If the pointer is larger than the integer, the representation will be truncated to fit in the integer.

ANSI C Standard: “The type of integer required to hold the difference between two pointers to elements of the same array, ptrdiff_t (6.3.6, 7.1.1).”

Implementation: ptrdiff_t is defined as an unsigned long short.

B.7 REGISTERS

ANSI C Standard: “The extent to which objects can actually be placed in registers by use of the register storage-class specifier (6.5.1).”

Implementation: The register storage-class specifier is ignored.

B.8 STRUCTURES AND UNIONS

ANSI C Standard: “A member of a union object is accessed using a member of a different type (6.3.2.3).”

Implementation: The value of the member is the bits residing at the location for the member interpreted as the type of the member being accessed.

ANSI C Standard: “The padding and alignment of members of structures (6.5.2.1).”

Implementation: Members of structures and unions are aligned on byte boundaries.

B.9 BIT-FIELDS

ANSI C Standard: “Whether a ‘plain’ int bit-field is treated as a signed int or as an unsigned int bit-field (6.5.2.1).”

Implementation: A “plain” int bit-field is treated as a signed int bit-field.

ANSI C Standard: “The order of allocation of bit-fields within a unit (6.5.2.1).”

Implementation: Bit-fields are allocated from least significant bit to most significant bit in order of occurrence.

ANSI C Standard: “Whether a bit-field can straddle a storage-unit boundary (3.5.2.1).”

Implementation: A bit-field cannot straddle a storage unit boundary.
B.10 ENUMERATIONS

ANSI C Standard: “The integer type chosen to represent the values of an enumeration type (6.5.2.2).”
Implementation: signed int is used to represent the values of an enumeration type.

B.11 SWITCH STATEMENT

ANSI C Standard: “The maximum number of case values in a switch statement (6.6.4.2).”
Implementation: The maximum number of values is limited only by target memory.

B.12 PREPROCESSING DIRECTIVES

ANSI C Standard: “The method for locating includable source files (6.8.2).”
Implementation: See 2.5.1 “System Header Files”.

ANSI C Standard: “The support for quoted names for includable source files (6.8.2).”
Implementation: See 2.5.2 “User Header Files”.

ANSI C Standard: “The behavior on each recognized #pragma directive (6.8.6).”
Implementation: See 2.9 “Pragmas”.
### Appendix C. Command-Line Summary

**Usage:** `mcc18 [options] file [options]

TABLE C.1: COMMAND-LINE SUMMARY (Continued)
Appendix D. MPLAB C18 Diagnostics

This appendix lists errors, warnings and messages generated by the MPLAB C18 compiler.

D.1 ERRORS

1002: syntax error, ‘%s’ expected
The syntax of the pre-processor construct was expecting the specified token. Common causes include typographical errors, missing required operands to the directive, and mis-matched parenthesis.

1013: error in pragma directive
MPLAB C18 was expecting the pragma being parsed to be complete, but did not see a new line. This would be caused by extra text following the pragma.

1014: attribute mismatch in resumption of section ‘%s’
MPLAB C18 requires that a previously declared section’s attribute must match those which are being specified in the current #pragma sectiontype directive. This error can also occur when the current #pragma sectiontype directive specifies overlay or access multiple times.

1016: integer constant expected for #line directive
The line number operand of the #line preprocessor directive must be an integer constant.

1017: symbol name expected in ‘interrupt’ pragma
The ‘save=’ clause expects a comma-delimited list of statically allocated in-scope symbol names which are to be saved and restored by the interrupt function being specified. Common causes include specifying a symbol which is not currently in scope, not including a header file which declares the symbol being referenced, and typographical errors in the symbol name.

1018: function name expected in ‘interrupt’ pragma
The name of a function to be declared as an interrupt is expected as the first parameter to the ‘interrupt’ pragma. The function symbol must be currently in scope and must take no parameters and return no value. Common causes include a missing prototype for the function being declared as an interrupt and typographical errors.

1019: ‘%s’ is a compiler managed resource - it should not appear in a save= list
The symbol named is not valid in a save= clause of an interrupt declaration. There are some locations which if saved/restored via a save= will produce aberrant code. These locations do not need additional context save and can be safely removed from the save= clause to correct the error.

1020: unexpected input following ‘%s’
Extra information exists on the given preprocessor construct.
1050: section address permitted only at definition
The absolute address in the location clause of the \texttt{#pragma sectiontype} directive may only be specified in the first pragma defining this section.

1052: section overlay attribute does not match definition
MPLAB C18 requires that a previously declared section's attribute must match those which are being specified in the current \texttt{#pragma sectiontype} directive.

1053: section share attribute does not match definition
MPLAB C18 requires that a previously declared section's attribute must match those which are being specified in the current \texttt{#pragma sectiontype} directive.

1054: section type does not match definition
MPLAB C18 has previously seen this section name, but it was of a different type (i.e., \texttt{code, idata, udata, romdata}).

1099: \texttt{%s} source code \texttt{#error} directive message

1100: syntax error
Invalid function type definition.

1101: lvalue required
An expression which designates an object is required. Common causes include missing parentheses and a missing '*' operator.

1102: cannot assign to 'const' modified object
An object qualified with 'const' is declared to be read-only data and modifications to it are therefore not allowed.

1103: unknown escape sequence '%s'
The specified escape sequence is not known to the compiler. Check the User's Guide for a list of valid character escape sequences.

1104: division by zero in constant expression
The compiler cannot process a constant expression that contains a divide by (or modulus by) zero.

1105: symbol '%s' has not been defined
A symbol has been referenced before it has been defined. Common causes include a misspelled symbol name, a missing header file that declares the symbol, and a reference to a symbol valid only in an inner scope.

1106: '%s' is not a function
A symbol must be a function name in order to be declared as an interrupt function.

1107: interrupt functions must not take parameters
When the processor vectors to an interrupt routine, no parameters are passed, so a function declared as an interrupt function should not expect parameters.

1108: interrupt functions must not return a value
Since interrupts are invoked asynchronously by the processor, there will not be a calling routine to which a value can be returned.
1109: type mismatch in redeclaration of ‘%s’
The type of the symbol declared is not compatible with the type of a previous declaration of the same symbol. Common causes include missing qualifiers or misplaced qualifiers.

1110: ‘auto’ symbol ‘%s’ not in function scope
Variables may only be allocated off the stack within the scope of a function.

1111: undefined label ‘%s’ in ‘%s’
The label has been referenced via a ‘goto’ statement, but has not been defined in the function. Common causes include a misspelled label identifier and a reference to an out of scope label, i.e., a label defined in another function.

1112: integer type expected in switch control expression
The control expression for a switch statement must be an integer type. Common causes include a missing ‘*’ operator and a missing ‘[’ operator.

1113: integer constant expected for case label value
The value for a case label must be an integer constant.

1114: case label outside switch statement detected
A ‘case’ label is only valid inside the body of a switch statement. Common causes include a misplaced ‘}’.

1115: multiple default labels in switch statement
A switch statement can only have a single ‘default’ label. Common causes include a missing ‘}’ to close an inner switch.

1116: type mismatch in return statement
The type of the return value is not compatible with the declared return type of the function. Common causes include a missing ‘*’ or ‘[’ operator.

1117: scalar type expected in ‘if’ statement
An ‘if’ statement control expression must be of scalar type, i.e., an integer or a pointer.

1118: scalar type expected in ‘while’ statement
A ‘while’ statement control expression must be of scalar type, i.e., an integer or a pointer.

1119: scalar type expected in ‘do..while’ statement
A ‘do..while’ statement control expression must be of scalar type, i.e., an integer or a pointer.

1120: scalar type expected in ‘for’ statement
A ‘for’ statement control expression must be of scalar type, i.e., an integer or a pointer.

1121: scalar type expected in ‘?:’ expression
A ‘?:’ operator control expression must be of scalar type, i.e., an integer or a pointer.

1122: scalar operand expected for ‘!’ operator
The ‘!’ operator requires that its operand be of scalar type.

1123: scalar operands expected for ‘||’ operator
The logical OR operator, ‘||’, requires scalar operands.

1124: scalar operands expected for ‘&&’ operator
The logical AND operator, ‘&&’, requires scalar operands.
1125: 'break' must appear in a loop or switch statement
A 'break' statement must be inside a 'while', 'do', 'for' or 'switch' statement. Common causes include a misplaced '}'.

1126: 'continue' must appear in a loop statement
A 'continue' statement must be inside a 'while', 'do', 'for' or 'switch' statement.

1127: operand type mismatch in '?' operator
The types of the result operands of the '?' operator must be either both scalar types, or compatible types.

1128: compatible scalar operands required for comparison
A comparison operator must have operands of compatible scalar types.

1129: [] operator requires a pointer and an integer as operands
The array access operator, '[]', requires that one operand be a pointer and the other be an integer, that is, for 'x[y]' the expression '*((x+y))' must be valid.

1130: pointer operand required for '*' operator
The '*' dereference operator requires a pointer to a non-void object as its operand.

1131: type mismatch in assignment
The assignment operators require that the result of the right hand expression be of compatible type with the type of the result of the left hand expression. Common causes include a missing '*' or '[' operator.

1132: integer type expected for right hand operand of '-=' operator
The '-=' operator requires that the right hand side be of integer type when the left hand side is of pointer type. Common causes include a missing '*' or '[' operator.

1133: type mismatch in '-=' operator
The types of the operands of the '-=' operator must be such that for 'x-=y' the expression 'x=x-y' is valid.

1134: arithmetic operands required for multiplication operator
The '*' and '*=' multiplication operators require that their operands be of arithmetic type. Common causes include a missing '*' dereference operator or a missing '[' index operator.

1135: integer operands required for division operator
The '/' and '/=' division operators require that their operands be of arithmetic type. Common causes include a missing '*' dereference operator or a missing '[' index operator.

1136: integer operands required for modulus operator
The '%' and '%=' division operators require that their operands be of integer type. Common causes include a missing '*' dereference operator or a missing '[' index operator.
integer types required for bitwise AND operator
The ‘&’ and ‘&=’ operators require that both operands be of integer type.
Common causes include a missing ‘*’ or ‘[]’ operator

integer types required for bitwise OR operator
The ‘|’ and ‘|=’ operators require that both operands be of integer type.
Common causes include a missing ‘*’ or ‘[]’ operator

integer types required for bitwise XOR operator
The ‘^’ and ‘^=’ operators require that both operands be of integer type.
Common causes include a missing ‘*’ or ‘[]’ operator

integer type required for bitwise NOT operator
The ‘~’ operator requires that the operand be of integer type. Common
causes include a missing ‘*’ or ‘[]’ operator

integer type expected for pointer addition
The addition operator requires that when one operand is of pointer type, the
other must be of integer type. Common causes include a missing ‘*’ or ‘[]’
operator.

type mismatch in ‘+’ operator
The types of the operands of the ‘+’ operator must be such that one operand
is of pointer type and the other is of integer type or both operands are of
arithmetic type.

pointer difference requires pointers to compatible types
When calculating the difference between two pointers, the pointers must
point to objects of compatible type. Common causes include missing
parentheses and a missing ‘[]’ operator.

integer type required for pointer subtraction
When the left hand operand of the subtraction operator is of pointer type,
the right hand operand must be of integer type. Common causes include a
missing ‘*’ or ‘[]’ operator.

arithmetic type expected for subtraction operator
When the left hand operand is not of pointer type, the subtraction operator
requires that both operands by of arithmetic type.

type mismatch in argument %d
The type of an argument to a function call must be compatible with the
declared type of the corresponding parameter

scalar type expected for increment operator
The increment operators require that the operand be a modifiable lvalue of
 scalar type.

scalar type expected for decrement operator
The decrement operators require that the operand be a modifiable lvalue of
 scalar type.

arithmetic type expected for unary plus
The unary plus operator requires that its operand be of arithmetic type

arithmetic type expected for unary minus
The unary minus operator requires that its operand be of arithmetic type
1151: struct or union object designator expected
The member access operators, '.' and '->' require operands of struct/union and pointer to struct/union, respectively.

1152: scalar or void type expected for cast
An explicit cast requires that the type of the operand be of scalar type and the type being cast to be scalar type or void type.

1153: cannot assign array type objects
An object of array type may not be directly assigned. Assignment is allowed only to array elements.

1154: parameter %d in '%s' must have a name
Parameters in a function definition must have an identifier declarator to name them. The naming declarator is not required in prototypes, but is in a definition.

1156: conflicting storage classes specified
A declaration may only specify a single storage class.

1157: conflicting base types specified
A declaration may only specify a single base type (void, int, float, et.al.). Multiple instances of the same base type is also an error (e.g., int int x;)

1158: both 'signed' and 'unsigned' specified
A type may include only one of 'signed' and 'unsigned.'

1160: function must be located in program memory
All functions must be located in program memory, as data memory is not executable.

1161: parameter storage class must be 'auto'
MPLAB C18 requires all parameters to be of 'auto' storage class. The MPLAB C17 construct of 'static' storage duration parameters is not supported by MPLAB C18.

1162: reference to incomplete tag '%s'
A forward reference struct or union tag cannot be referenced directly in a declaration. Only pointers to a forward referenced tag may be declared.

1163: invalid type specification
The type specification is not valid. Common causes include typographic errors or misuse of a typedef type. e.g., “int enum myEnum xyz;” has an invalid type specification.

1164: redefinition of enum tag '%s'
An enumeration tag may only be defined once. Common causes include multiple inclusions of a header file which defines the enumeration tag.

1165: reference to undefined enumeration tag '%s'
An enumeration tag must be defined prior to any declarations which reference it. Unlike structure and union tags, forward references to enumeration tags are not allowed.

1166: anonymous members allowed in unions only
An anonymous structure member may be declared only as a member of a union.

1167: non-integral type bitfield detected
The type of a bitfield member of a structure must be an integral type.
1171: bitfield width greater than 8 detected
A bitfield must fit within a single storage unit, which for MPLAB C18 is a byte. Thus, a bitfield must contain 8 or fewer bits.

1172: enumeration value of ‘%s’ does not match previous
When the same enumeration constant name is used in multiple enumeration tags, the value of the enumeration constant must be the same in each enumeration.

1173: cannot locate a parameter in program memory, ‘%s’
Since all parameters are located on the stack, it is not possible to locate a parameter in program memory. Common causes include a mis-typed pointer to program memory declaration.

1174: local ‘%s’ in program memory can not be ‘auto’
A local variable which is located in program memory must be declared as static or extern, as ‘auto’ local variables must be located on the stack.

1175: static parameter detected in function pointer ‘%s’
Function pointers require parameters be passed via the stack. When compiling with static locals enabled, declare parameters for function pointers and for functions whose addresses are assigned to function pointers explicitly to ‘auto’.

1176: the sign was already specified
A type may include only one ‘signed’ or ‘unsigned’.

1200: cannot reference the address of a bitfield
The address of a bitfield member of a structure cannot be referenced directly.

1201: cannot dereference a pointer to ‘void’ type
The ‘*’ dereference operator requires a pointer to a non-void object as its operand.

1202: call of non-function
The operand of the ‘()’ function call post-fix operator must be of type ‘pointer to function.’ Most commonly, this is a function identifier. Common causes include missing scope parentheses.

1203: too few arguments in function call
To call a function, the number of arguments passed must match exactly the number of parameters declared for the function.

1204: too many arguments in function call
To call a function, the number of arguments passed must match exactly the number of parameters declared for the function.

1205: unknown member ‘%s’ in ‘%s’
The structure or union tag does not have a member of the name requested. Common causes include a misspelled member name and a missing member access operator for a nested structure.

1206: unknown member ‘%s’
The structure or union type does not have a member of the name requested. Common causes include a misspelled member name and a missing member access operator for a nested structure.
1207:  tag ‘%s’ is incomplete
An incomplete struct or union tag cannot be referenced by the member
access operators. Common causes include a misspelled structure tag
name in the symbol definition.

1208:  ‘#pragma interrupt’ detected inside function body
The ‘interrupt’ pragma is only available at file level scope.

1209:  unknown function ‘%s’ in #pragma interrupt
The ‘interrupt’ pragma requires that the function being declared as an
interrupt have an active prototype when the pragma is encountered

1210:  unknown symbol ‘%s’ in interrupt save list
The ‘interrupt’ pragma requires that symbols listed in the ‘save’ list must be
declared and in scope

1211:  missing definition for interrupt function ‘%s’
The function was declared as an interrupt, but was never defined. The
function definition of an interrupt function must be in the same module as
the pragma declaring the function as an interrupt.

1212:  static function ‘%s’ referenced but not defined
The function has been declared as static and has been referenced
elsewhere in the module, but there is no definition for the function present.
Common causes include a misspelled function name in the function
definition.

1213:  initializer list expected
The symbol being initialized requires a brace-enclosed initializer list, but a
single value initializer was found.

1214:  constant expression expected in initializer
The initializer value for a statically allocated symbol
must be a constant
expression.

1215:  initialization of bitfield members is not currently supported
Bitfield structure members cannot currently be initialized explicitly.

1216:  string initializer used for non-character array object
A string literal initializer is only valid for initializing
objects of type ‘array of char’ or type ‘pointer to char’ (either can be unsigned char as well).

1218:  extraneous initializer values
The count of initializer values does not agree with the number of expected
values based on the type of the object being initialized. There are too many
values in the initializer list.

1219:  integer constant expected
A constant expression of integral type was expected, but an expression of
non-integral type or a non-constant expression was found.

1220:  initializer detected in typedef declaration of ‘%s’
A typedef declaration cannot include initializers

1221:  empty initializer list detected
An initializer list cannot be empty. There must be one or more initializer
values between the braces.
MPLAB C18 Diagnostics

1250: ‘%s’ operand %s must be a literal
The specified operand for the opcode must be a literal value, not a symbol reference.

1251: ‘%s’ operand count mismatch
The number of operands found for the specified opcode does not match the number of operands expected. Unlike MPASM, the MPLAB C1x in-line assembler expects all operands to be explicitly specified. There are no default values for operands such as the access bit or destination bit.

1252: invalid opcode ‘%s’ detected for processor ‘%s’
The opcode specified is not valid for the target processor. Common causes include porting in-line assembly code from a processor with a different instruction set (e.g., PIC17CXX to PIC18CXX) and typographical errors in the spelling of the opcode.

1253: constant operand expected
Operands to in-line assembly opcodes must resolve to a constant expression, where a constant expression is defined as a literal constant or a statically allocated symbol reference optionally plus or minus an integer constant. Common causes include the use of a dynamically allocated symbol (‘auto’ local variables and parameters) as the operand to an in-line assembly opcode.

1300: stack frame too large
The size of the stack frame has exceeded the maximum addressable size. Commonly caused by too many local variables allocated as ‘auto’ storage class in a single function.

1301: parameter frame too large
The size of the parameter frame has exceeded the maximum addressable size. Commonly caused by too many parameters being passed to a single function.

1302: old style function declarations not supported
MPLAB C18 does not currently support the old K&R style function definitions. The in-line parameter type declarations recommended by the ANSI standard should be used instead.

1303: ‘near’ symbol defined in non-access qualified section
Statically allocated variables allocated into a non-access qualified section cannot be accessed via the access bit, and therefore defining them with the ‘near’ range qualifier would result in incorrect access to the location.

1500: unable to open file ‘%s’
The compiler was unable to open the named file. Common causes include misspelled filename and insufficient access rights.

1501: unable to locate file ‘%s’
The compiler was unable to locate the named file. Common causes include misspelled filename and misconfigured include path.

1502: unknown option ‘%s’
The specified command-line option is not a valid MPLAB C1X option.

1503: multi-bank stack supported only on 18Cxx core
The software stack can cross bank boundaries only on the 18CXX processors.
1504: redefinition of ‘%s’
The same function name may not have multiple definitions.

1505: redeclaration of ‘%s’
The same variable name may not have multiple defining declarations.

1512: redefinition of label ‘%s’
The same label may not have multiple definitions in the same function.

1900: %s processor core not supported
The compiler does not currently support the specified processor core.
Commonly caused by a misspecification of processor name or an invocation of the incorrect compiler executable.
D.2 WARNINGS

2001: non-near symbol ‘%s’ declared in access section ‘%s’
Statically allocated variables declared into an access qualified section will always be placed by the linker into access data memory, and can therefore always be qualified with the ‘near’ range qualifier. Not specifying the ‘near’ range qualifier will not cause incorrect code, but may result in extraneous bank select instructions.

2002: unknown pragma ‘%s’
The compiler has encountered a pragma directive which is not recognized. As per ANSI/ISO requirements, the pragma is ignored. Common causes include misspelled pragma names.

2052: unexpected return value
A return of a value statement has been detected in a function declared to return no value. The return value will be ignored.

2053: return value expected
A return with no value has been detected in a function declared to return a value. The return value will be undefined.

2054: suspicious pointer conversion
A pointer has been used as an integer or an integer has been used as a pointer without an explicit cast.

2055: expression is always false
The control expression of a conditional statement evaluates to a constant false value

2056: expression is always true
The control expression of a conditional statement evaluates to a constant true value

2057: possibly incorrect test of assignment
An implicit test of an assignment expression, (e.g., ‘if(x=y)’ is often seen when an ‘==’ operator has been used when a ‘!=' operator was intended).

2058: call of function without prototype
A function call has been made without an in-scope function prototype for the function being called. This can be unsafe, as no type-checking for the function arguments can be performed.

2059: unary minus of unsigned value
The unary minus operator is normally only applied to signed values.

2060: shift expression has no effect
Shifting by zero will not change the value being shifted.

2061: shift expression always zero
The number of bits that the value is being shifted by is greater than the number of bits in the value being shifted. The result will always be zero.

2062: ‘->’ operator expected, not ‘.’
A struct/union member access via a pointer to struct/union has been performed using the ‘.’ operator.

2063: ‘.’ operator expected, not ‘-’
A direct struct/union member access has been performed using the ‘-’ operator.
2064: static function ‘%s’ not defined
The function has been declared as static, but there is no definition for the function present. Common causes include a misspelled function name in the function definition.

2065: static function ‘%s’ never referenced
The static function has been defined, but has not been referenced.

2066: type qualifier mismatch in assignment
Pointer assignment where the source and destination pointers point to objects of compatible type, but the source pointer points to an object which is ‘const’ or ‘volatile’ qualified and the destination pointer does not.

2067: type qualifier mismatch in argument %d
The argument expression is a pointer to a ‘const’ or ‘volatile’ qualified version of a compatible type to the parameter’s type, but the parameter is a pointer to a non-‘const’ or ‘volatile’ qualified version.

2068: obsolete use of implicit ‘int’ detected.
The ANSI standard allows a variable to be declared without a base type being specified, e.g., “extern x;”, in which case a base type of ‘int’ is implied. This usage is deprecated by the standard as obsolete, and therefore a diagnostic is issued to that effect.

2069: enumeration value exceeds maximum range
An enumeration value has been declared which is not expressible in a ‘signed long’ format and the enumeration tag has negative enumeration values. An ‘unsigned long’ representation will be used for the enumeration, but relative comparisons of those enumeration constants which have negative representations may not behave as expected.

2070: constant value %d is too wide for bitfield and will be truncated
The given value cannot fit into the bitfield. Truncation by ANDing with the size of the bitfield was performed.

2071: %s cannot have ‘overlay’ storage class; replacing with ‘static’
Parameters with ‘overlay’ storage class are not permitted at this time. When the default local storage class is ‘overlay’, the ‘static’ storage class will be assigned to parameters.

2072: invalid storage class specifier for %s; ignoring
The storage class specifier used is not permitted for this declaration.

2073: null-terminated initializer string too long
The null-terminated initializer string cannot fit in the array object.
D.3 MESSAGES

3000: test of floating point for equality detected
Testing two floating point values for equality will not always yield the desired results, as two expressions which are mathematically equivalent may evaluate to slightly different values when computed due to rounding error.

3001: optimization skipped for '%s' due to inline assembly
Functions which contain inline assembly are not run through the optimizer since inline assembly may contain constructs which would result in the optimizer performing incorrectly.

3002: comparison of a signed integer to an unsigned integer detected
Comparing a signed integer value to an unsigned integer value may yield unexpected results when the signed value is negative. To compare an unsigned integer to the binary equivalent representation of the signed value, the signed value should first be explicitly cast to the unsigned type of the same size.
Glossary

A

absolute section
A section with a fixed address that cannot be changed by the linker.

access memory
Special general purpose registers on the PIC18 PICmicro microcontrollers that allow access regardless of the setting of the bank select register (BSR).

address
The code that identifies where a piece of information is stored in memory.

anonymous structure
An unnamed object.

ANSI
American National Standards Institute

assembler
A language tool that translates assembly source code into machine code.

assembly
A symbolic language that describes the binary machine code in a readable form.

assigned section
A section that has been assigned to a target memory block in the linker command file.

asynchronously
Multiple events that do not occur at the same time. This is generally used to refer to interrupts that may occur at any time during processor execution.

B

binary
The base two numbering system that uses the digits 0-1. The right-most digit counts ones, the next counts multiples of 2, then $2^2 = 4$, etc.

C

central processing unit
The part of a device that is responsible for fetching the correct instruction for execution, decoding that instruction, and then executing that instruction. When necessary, it works in conjunction with the arithmetic logic unit (ALU) to complete the execution of the instruction. It controls the program memory address bus, the data memory address bus, and accesses to the stack.

compiler
A program that translates a source file written in a high-level language into machine code.
conditional compilation
The act of compiling a program fragment only if a certain constant expression, specified by a preprocessor directive, is true.

CPU
Central Processing Unit

E
endianness
The ordering of bytes in a multi-byte object.

error file
A file containing the diagnostics generated by the MPLAB C18

F
fatal error
An error that will halt compilation immediately. No further messages will be produced.

frame pointer
A pointer that references the location on the stack that separates the stack-based arguments from the stack-based local variables.

free-standing
An implementation that accepts any strictly conforming program that does not use complex types and in which the use of the features specified in the library clause (ANSI '89 standard clause 7) is confined to the contents of the standard headers <float.h>, <iso646.h>, <limits.h>, <stdarg.h>, <stdbool.h>, <stddef.h>, and <stdint.h>.

H
hexadecimal
The base 16 numbering system that uses the digits 0-9 plus the letters A-F (or a-f). The digits A-F represent decimal values of 10 to 15. The right-most digit counts ones, the next counts multiples of 16, then 16^2 = 256, etc.

high-level language
A language for writing programs that is further removed from the processor than assembly.

I
ICD
In-Circuit Debugger

ICE
In-Circuit Emulator

IDE
Integrated Development Environment

IEEE
Institute of Electrical and Electronics Engineers

interrupt
A signal to the CPU that suspends the execution of a running application and transfers control to an ISR so that the event may be processed. Upon completion of the ISR, normal execution of the application resumes.
interrupt service routine
A function that handles an interrupt.

ISO
International Organization for Standardization

ISR
Interrupt Service Routine

L
latency
The time between when an event occurs and the response to it.

librarian
A program that creates and manipulates libraries.

library
A collection of relocatable object modules.

linker
A program that combines object files and libraries to create executable code.

little endian
Within a given object, the least significant byte is stored at lower addresses.

M
memory model
A description that specifies the size of pointers that point to program memory.

microcontroller
A highly integrated chip that contains a CPU, RAM, some form of ROM, I/O ports, and timers.

MPASM assembler
Microchip Technology's relocatable macro assembler for PICmicro microcontroller families.

MPLIB object librarian
Microchip Technology's librarian for PICmicro microcontroller families.

MPLINK object linker
Microchip Technology's linker for PICmicro microcontroller families.

O
object file
A file containing object code. It may be immediately executable or it may require linking with other object code files, e.g. libraries, to produce a complete executable program.

object code
The machine code generated by an assembler or compiler.

octal
The base 8 number system that only uses the digits 0-7. The right-most digit counts ones, the next digit counts multiples of 8, then \(8^2 = 64\), etc.
pragma
A directive that has meaning to a specific compiler.

RAM
Random Access Memory
random access memory
A memory device in which information can be accessed in any order.
read only memory
Memory hardware that allows fast access to permanently stored data but prevents addition to or modification of the data.

ROM
Read Only Memory
recursive
Self-referential (e.g., a function that calls itself). See recursive.
reentrant
A function that may have multiple, simultaneously active instances. This may happen due to either direct or indirect recursion or through execution during interrupt processing.
relocatable
An object whose address has not been assigned to a fixed memory location.
runtime model
Set of assumptions under which the compiler operates.

section
A portion of an application located at a specific address of memory.
section attribute
A characteristic ascribed to a section (e.g., an access section).
special function register
Registers that control I/O processor functions, I/O status, timers, or other modes or peripherals.
storage class
Determines the lifetime of the memory associated with the identified object.
storage qualifier
Indicates special properties of the objects being declared (e.g., const).

vector
The memory locations that an application will jump to when either a reset or interrupt occurs.
